increased with the increase of rating as shown in Tests 4, 5 and 6. This increase in efficiency with increase in rating is accompanied by a reduction in dry-gas losses, and a reduction in the losses unaccounted for. The CO loss increases, as would be expected, as the rate of burning coal increases. The decrease in dry-gas loss with increase in rating is again due to the more efficient utilization of the available draft at higher ratings.

Under the modified operating conditions with bituminous coal the efficiency increases with a decrease in rating. The increase in efficiency is accompanied by a decrease in dry-gas losses, and a decrease in loss due to carbon monoxide in the flue gases.

The decrease in dry-gas losses with decrease in rating, just the reverse of the trend of the dry-gas losses under the original conditions, is brought about by the decrease in pressure difference between the inside and the outside of the setting as the damper is closed. This decrease in pressure difference decreases the influx of cold air through leaks in the setting, and consequently results in less dilution and cooling of the products of combustion, and therefore less waste of heat.

A Desirable Condition

The fact that the efficiency increases with a decrease in rating under the modified operating conditions is an especially desirable condition because of the low average rate of working the boilers in the plant under consideration. The average rate of working the boilers was estimated to be 75 per cent. of builder's nominal rating. Thus the gain in efficiency due to modifying the conditions was 13.2 per cent. over the original conditions with anthracite coal, and approximately 9 per cent. over the original conditions with bituminous coal.

Thus from each 176 heat units in the anthracite coal, 100 heat units were given to the steam; and from each 176 heat units in the bituminous coal, 104 heat units were given to the steam before the modifications, and 123 heat units were given to the steam after the modifications.

The cost of coal per 1,000 lb. of steam under the original operating conditions at the average rate of boiler working was $0.7050 with anthracite and $0.4225 with bituminous coal. After modifying the conditions the cost of bituminous coal per 1,000 lb. of steam was $0.3540. These figures were obtained from the costs of coal obtained from the delivery records for an eleven-month period. During that period 2,653 long tons of bituminous coal were delivered at a total cost of $19,535.16, and 1,957 long tons of pea-size anthracite at a total cost of $20.121.31.

When the capacity of an injector decreases slowly week by week, it indicates that the combining tubes are becoming coated with scale. Soaking the tubes or injector in a strong soda solution will help loosen the scale.

What's Wrong With Stokers?

Not Much When Engineers Firmly Declare Any Type to be an Improvement Over Hand Firing

CANADIAN engineers can well remember when a one-armed man could count all the successful makers of stokers on his fingers, and bearing this in mind the recent developments in design and the expansion of the field are remarkable.

This development has followed the usual course of conflicting opinion between maker and user, the manufacturer often regarding the engineer, with his suggestions for improvements, as in the class of the old lady who moved spring and fall for 20 years hoping to find a dwelling with a southern exposure on all four sides, and the engineer in turn believing the maker was only interested in selling large rectangular blocks of cast iron at a very excessive price per pound.

User Often Wrong

Of the two, however, the user in the past was more frequently wrong not only because there were more of him but because he demanded an impossible standard of performance from a fixed mechanism handling a very variable material.

To-day however, it is very evident that times and results have changed, for the engineer joins with the manufacturer in praising the economies in fuel and labor and the efficiency in combustion possible with modern stoker installation.

"Speaking on behalf of stokers, I can't see how you can begin to compare them with the hand-fed type," says W. Clark, chief engineer, Toronto Carpet Co.

Mr. Clark thinks there are three outstanding points in favor of them. First—the saving of labor; Second—higher evaporation; Third—greater efficiency in the plant.

The Toronto plant contains four stokers, each of 421 h.p. Each stoker is supplied by natural draft.

Can Be No Doubt

"As to the superiority of mechanical stoking over hand firing, there can be no doubt. When local conditions are considered, and the most suitable stoker installed to meet those conditions, there is nothing better. With proper stoker selection and proper operation, hand firing hasn't a show against mechanical stokers. Having operated, installed and tested stokers, I am of the firm opinion that they can't be beaten." This is the opinion expressed by R. McLaren, chief engineer, Massey-Harris Co.

John H. Stananought, chief engineer, Canadian Dyers' Association, expresses his opinion that "stokers of the type installed in our plant are very economical. They are labor saving, smokeless and can cope with variable loads. I might say that the engine is automatically controlled by a regulator, and the steam pressure never varies beyond 3 lbs. Comparing them with hand firing I must say that it is a marked improvement and beneficial both to manufacturer and firemen." The equipment in this plant is as follows:—Two 400 h.p. vertical water tube boilers with stokers, 3 retorts under each boiler. Each stoker supplied by forced draft.

Ends Useless Toil

"In comparison with hand firing, I consider any type of standard make of stokers an improvement, both as regards fuel economy, smoke abatement and the absence of the arduous duties incidental to hand firing. We are at present operating stokers, installed under 4—150 h. p. return tubular boilers. The type of stoker we have installed is very well suited to a plant of moderate size, and in operation is an imitation of the expert hand fireman, without the detrimental effects of hand firing, arising through the frequent opening of the furnace doors. We are reasonably sure of the superiority of the stoker over hand firing, because we can get a practical demonstration by reverting to hand firing at any time." The practical opinion of H. Potter, chief engineer, Hinde and Dauch Paper Co.

Trade Catalogs

Recording gages for pressure and vacuum, Bristol Company, Waterbury, Conn. Catalogue No. 1006 contains 84 pages of text and illustrations. Besides the different types of instruments shown, there is a variety of charts listed which adapt the gages to practically every application where pressure of liquids, gases, steam or air are required to be measured.

Thomas A. Gerner, of Newmarket, has been appointed superintendent of the gas works in Waterloo. Gas in Waterloo is unusually expensive and the new superintendent will immediately reorganize the department and effect economies, which, it is hoped, will result in a considerable reduction in the price of gas.

To build a new fire with a minimum of smoke when bituminous, high-volatile coal is used, put a thin layer of green coal on the grate and cover with shavings and wood soaked in crude oil. Ignite adding as little green fuel as possible, the aim being to begin the fire by burning the top of the layer, thus making the volatile gases and vapors pass through the hottest zone. Keep the fire door open as much as possible to prevent smoke.

Why Feed Water Heating Saved $30,000 a Year!

Whether Heat Utilized is Waste or Not—It's Good Business, for the Hotter the Water is When it Enters the Boiler the Sooner It Will Boil

* By ROBERT McLAREN

THAT it is good business from the standpoint of economy to heat the boiler feed water with waste heat, hardly anybody will deny. That it is good business to heat the feed water even when the heat employed in the process is not waste heat, not every engineer is aware.

But it is good business and good engineering practice for the reason that the circulation of the water in the boiler is more rapid when it is boiling than when it is not and the hotter the water is when it enters the boiler the sooner it will reach boiling point.

Heating of the feed water may be accomplished in heaters of the Hoppes type in which live steam is in contact with the water, both water and steam being at boiler pressure. This would be a live steam feed water heater.

Or it may be done in heaters in which exhaust steam is used, the heater being between the feed pump and the boiler and the water being at boiler pressure.

Exhaust Steam Heater

Or the heating may be done in a heater in which the water and exhaust steam are in direct contact. The heater in this case would be between the pump and the boiler, the water would not be at boiler pressure, but either at atmospheric pressure during the summer or at the pressure carried on the heating system during the cold season. The pump would draw water from the heater instead of pumping it through the heater.

With the closed heater no attempt may be made to remove the oil from the exhaust steam in which case the condensate produced in the heater will have to be wasted unless the engine happens to be a turbine (in which case the steam will be oil free and the condensate may be used for boiler feed) and the only ill effect of the oil in the steam will be a more or less lowering of the efficiency of the heater through coating the heating surfaces with oil.

Oil Separator Necessary

With the open heater an oil separator is necessary to remove the oil from the exhaust steam. This will be done more or less thoroughly although there are separators that will remove the oil with sufficient thoroughness to permit the use of the exhaust steam and condensate for textile manufacturing and, of course, that should be good enough for boiler feed purposes.

The kind of cylinder oil used will have an effect on the thoroughness with which the separator will do its work. A straight mineral oil is more easily removed from exhaust steam than a compounded oil but if the steam is wet compounding is necessary as a straight mineral oil will not form an emulsion with the moisture in the steam while a compounded oil will and lubrication of the cylinder wall is thereby effected.

Filtered Oil Usage

Compounding also makes the oil more easily atomized but this result can be obtained by using filtered oil. The fuel saving possible by heating the feed water amounts to about 1 per cent. for each 11° rise in the temperature of the feed water. This applies to any heater in which waste heat is used.

In the open heater there is another saving, and that is the condensate produced in the heater. Roughly, to make 7 lbs. of hot boiler feed water the closed heater requires 7 lbs. of cold water and 1 1/6 lbs. of steam, the latter being thrown away unless the engine is a turbine, in which case it may be saved as already explained, whereas the open heater requires 6 lbs. of cold water and 1 lb. of exhaust steam, assuming that the water is heated from 50° to 210° in both cases. From this it is evident that with the open heater 1/7 of the boiler feed is distilled water which requires no boiler compound.

The following table shows what the open heater does in heating water from various temperatures to 210° F.

Horsepower Ratio

A boiler horsepower is assumed to be the evaporation of 30 lbs. of water. It will be noticed columns 2 and 3, pounds of steam required + pounds of city water required = 30.

Water entering Heater at	Pounds of Exhaust Steam Condensed	Pounds of City Water Required	Saving of Water By the Use of Open Heater
32° F.	4.67	25.33	15.9%
35	4.60	25.40	15.7
40	4.49	25.51	15.0
45	4.37	25.63	14.6
50	4.26	25.74	14.2
55	4.15	25.85	13.8
60	4.03	25.97	13.4
65	3.91	26.09	13.0
70	3.80	26.20	12.7
75	3.68	26.32	12.3
80	3.56	26.44	11.9
85	3.44	26.56	11.5
90	3.31	26.69	11.0
95	3.19	26.81	10.6
100	3.07	26.93	10.2
110	2.81	27.19	9.4
120	2.56	27.44	8.5
130	2.29	27.71	7.6
140	2.02	27.98	6.7
150	1.75	28.25	5.8
160	1.47	28.53	4.9
170	1.19	28.81	4.0
180	0.93	29.07	3.1
190	0.63	29.37	2.1
200	0.32	29.68	1.1
210	0.00	30.00	0.0

The open heater has another advantage in that if it is properly ventilated it will heat the water to within 1 or 2 degrees of the temperature of the exhaust steam while the closed heater will not heat it to within 15° of the exhaust steam temperature and even that performance requires a more liberal ratio of heating surface to horsepower rating than most heater builders are willing to allow.

Boiler Compound Cut

At a temperature of 200° and over it is well known that the carbonates are precipitated, further reducing the amount of boiler compound required. Any case of oil in boilers of which I am aware where an open heater was used, was not due to failure of the oil separator to remove the oil from the steam but due to failure to remove the separated oil from the trap, and should not be regarded as a deficiency of the heater or separator.

As an illustration, the following will probably suffice:

In a plant of which I once took charge the safety idea was carried to such a length that all the condensation from the heating system was run into the sewer. There was also a closed heater that heated the water to about 145°, the condensate from which, of course, also ran to the sewer. As the floor area of the plant was about 28 acres, you will readily understand that it was not a small one. By means of a vacuum pump condensation was removed from dry kilns at least 500 feet from the engine room and dumped into the sewer, at the engine room door. During the day all the exhaust steam was turned into the heating system but the supply was insufficient, on very cold days 30% or more of the heating being done with live steam.

At night and during week ends and holidays, of course, all the heating was done with live steam, but everything went to the sewer. I had an open heater installed and the water was heated as high as 220°, depending on the back pressure carried for the heating system. I also had the heating system overhauled and the boiler settings improved, the changes resulting in annual saving of more than $30,000.

Safety First in Boiler Rooms

Practical Methods of Adjusting the Blow Off Pressure of Three Types of Safety Valves

BY GEORGE A. BROWN*

IN ANY discussion of appliances necessary in a boiler room, it is natural that one of the first to come to mind should be the safety valve, the purpose of which is to relieve the boiler of excess pressure and prevent the steam rising above a certain point.

When the boiler is generating steam faster than it can be used it is plain that a large quantity of steam is being built up in the steam space and the result is a steadily increasing pressure. If this condition were to continue the boiler would eventually explode from a pressure it could not withstand, and so it is the function of the safety valve to eliminate such danger.

There are three types of safety valves—the dead weight, the weight on a lever, and the spring loaded. The weight or spring is so adjusted in the different types that when the steam reaches the desired pressure the seat raises and allows the surplus steam pressure to escape.

The dead weight form of safety valve and the weight-on-lever type have been almost superseded by the spring-loaded type, as the boiler laws of various countries indicate that this type of safety valve is almost fool-proof.

Difficult to Overload

Dead-weight safety valves are difficult to overload as the weights are so large that it requires a considerable added weight to raise the blowing-off pressure.

As an example, let us decide what load would have to be put on a 3-in. valve to allow it to blow off at 90 pounds per square inch by multiplying the area of the valve in sq. inches by the pressure.

For example:

Weight required = 3 x 3 x .7854 x 90 = 636.17 pounds.

What weight is required for the same valve to blow off at 75 pounds per sq. inch?

Weight required = 3 x 3 x .7854 x 75 = 529.14 pounds.

It, therefore, can easily be seen that it requires considerable added weight to raise the pressure, as the 90-pound pressure takes 107 pounds more to hold down the valve than it does to hold down 75 pounds pressure.

The weight-and-lever safety valve, more commonly called the ball-and-lever type, is often found in old plants. Experience shows that the position to place the ball on the lever is usually found by trial in preference to calculations. The majority of safety valve levers are notched, and below the notch a number is to be found corresponding to the pressure per sq. inch at which the valve will blow off when the weight or ball is placed in that notch.

Since it is possible that the notches are not correctly located or that the weight of the ball is not for that particular lever, it is good practice to determine the position of the weight on the lever by actual trial.

If you get the steam pressure up to the point you want the safety valve to blow off at, slide the weight along the lever until the valve just commences to blow off, then lock or fasten the weight so that it cannot be accidentally moved. If, however, you prefer to set the weight and lever safety valve by calculation, the following formula applies:

$$P=\frac{W\times D}{A\times d} \text{ or } W=\frac{A\times P\times d}{D}$$

$$\text{or } D=\frac{A\times P\times d}{W}$$

P=Pressure per sq. inch on valve, which will balance ball.

W=Weight of ball in pounds.

D=Distance of ball from fulcrum in inches.

d=distance of valve stem from fulcrum in inches.

A=Area of valve in sq. inches.

The engineer in middle life should have a more reliable mental process than the young man. If he acquires facts and methods of calculation less rapidly, he usually grasps them more firmly. Besides he has a wealth of practical experience that helps him to understand and a maturity of judgment which aids him in deciding the particular needs of his plant. Age is no drawback, it is an asset.

I have purposely omitted the weight of the valve seat and stem, also the weight of the lever at its centre of gravity because they make so little difference in the solution of the problem as to be almost negligible.

To Make My Point Clear

What pressure will a safety valve blow off at with an area of 7.069 inches with the valve stem 2.5 in. from fulcrum?

The valve and stem weighs 1.5 pounds, the lever weighs at its centre of gravity 6 pounds. The length to centre of gravity, 9 inches, weight of ball, 48 pounds, placed 30 inches from the fulcrum.

A Practical Example

The correct way to do this is to multiply the weight of the ball, valve, stem, and lever, each by the distance of its centre of gravity from the fulcrum, and add the result. Multiply the area of the valve by the distance of its centre from the fulcrum, dividing the result into the sum of the products. The answer then will be the pressure the valve will blow off at.

Weight of ball 48 lbs. × 30 inch from the fulcrum.

Weight of valve and stem 1.5 lbs. × 2.5 inches from fulcrum.

Weight of lever at C. gravity 6 lbs. × 9 inches from fulcrum.

We then have:

48 × 30 = 1440.
1.5 × 2.5 = 3.75
6 × 9 = 54

Sum of products = 1497.75

Area of valve 7.069 × 2.5, distance of stem from fulcrum 7.069 × 2.5 = 17.6725; this divided into the above product gives the pressure to make the valve blow.

17.66725)1497.7500(84.74
1413800
839500
707000
1325000
1237075
87925.

Now we will seek to solve the same problem by the first formula:

$$P=\frac{W\times D}{A\times d}=P=\frac{48\times 30}{7.069\times 2.5}=\frac{1440}{17.6725}$$

$$\frac{1440}{17.6725}=81.48 \text{ lbs.}$$

pressure the safety valve blows off at, or a difference of but 3 lbs.

In the spring loaded safety valve the valve seat is held down by a spring and the blow off pressure may be changed by altering the tension on the spring. The general rule, if it is necessary to change the blow off pressure, is that the spring tension may be changed within 10 pound limits. That is to say, if you had a 100 pound spring and wished to change it to 120 lbs., you would have to get a 120-pound spring from the manufacturer, but if you only wanted to change it to 105 pounds, then you could screw down the spring tension to make it blow off at 105 pounds.

Rules Must Vary

It is doubtful if the spring loaded safety valve can be computed by any special rule, because a spring will yield according to the shape, size, and material it is made of, as well as its diameter, pitch and number of coils. It is only necessary to consider the varied materials springs are made of to realize what a problem it would be to determine a standard rule for computing every type of spring loaded safety valve.

Spring loaded safety valves are practically foolproof because after they have been set for the desired pressure they can be locked so that the boiler attendant cannot make them hold down more pressure than the amount required, whereas with the dead weight and the ball and lever safety valve it is a simple matter to put on more weight to raise the pressure from which they are set at.

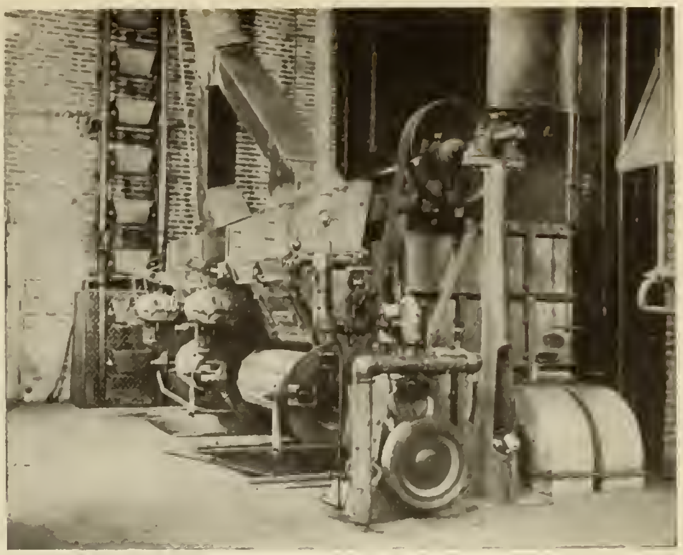
Babcock & Wilcox Compartment Type Chain Grate Stokers



Showing Stokers Installed by the Berliner Gramophone Co., Montreal

Balanced Draft When it is required to burn low grade fuels at maximum efficiency these stokers are operated on Balanced Draft. In considering the question of Balanced Draft it has to be remembered that the heating value and general characteristics of fuels vary within very wide limits. Further, the amount of heat imparted to a boiler depends on the number of heat units liberated per square foot of area in a given time.

The primary object of Balanced Draft is to consume a larger quantity of low grade fuel per square foot of grate area than is possible when working under natural draft conditions. The necessity for this increased consumption will vary in intensity according to the characteristics and heating value of the fuel to be consumed, and a naturally free burning coal will not require so much draft as one containing a low percentage of volatile matter. Whilst, therefore, Balanced Draft is not necessary for efficiently burning an average quality coal, it is often essential for the efficient combustion of very low grade fuels or of fuels containing a low percentage of volatile matter.

Natural Draft This stoker is so constructed that although Balanced Draft can be applied when the class of fuel makes this necessary, it still has all the advantages of the standard Chain Grate in that it operates economically on Natural Draft when using average coal.

Odd Questions and Their Answers

Queries are invited on the every-day problems of engineers in all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped a fellow engineer and a pleasure for us to pass on the data.

VALVE ADJUSTMENT

Will you please answer the following question in Power House. By what method, in a busy shop, where time is a paramount factor, can the slide valve and Meyer cut-off valve be set and adjusted in an Ingersoll-Rand Type C2 compressor?—J. N.

Answer:—The main valve should be set to open on dead centre or a little late; as late as ¾ in. on the stroke would be an advantage rather than otherwise. Under no circumstances should the main valve be given "lead." This is a mistake that any engineer familiar only with steam engines is pretty sure to make. The compression in the air cylinder makes it not only unnecessary but absolutely harmful to have compression in the steam cylinder, because in that case you get a double load on the bearings just at the end of the stroke which is very liable to cause a knock. The machine will therefore run smoothest if the steam admission is a little late.

The machine should be turned in the direction of rotation past the dead centre until the crosshead has moved say, ½ in., then the main valve should be just opening. Then turn the machine over to the other end and see that the other end of the valve opens at the same point on the other stroke. This is all that is required in connection with the main valve. Then turn the machine in the direction of rotation to half stroke and set the cut-off indicator half stroke and see that the valve is just closing. Then turn the machine over until the crosshead is halfway on the other stroke and see that the other cut-off valve is just closing. If the cut-off is unequal the nut lock can be taken off one of the crosshead nuts and the cut-off adjusted.—H. V. Haight, Chief Engineer, Canadian Ingersoll-Rand Co.

KILN-DRYING APPARATUS

I recently had an inquiry concerning the steaming of a dry kiln in a tile factory, as to size of boiler and the best method of installation. My intentions are to steam an open trough, 30 x 18 inches, and 6 inches deep, on each side of the room, with coils. Room is 30 x 44 x 8½ ft., and at present it is heated with hot water plant, which will be left in for that purpose. The steam must rise from troughs into said room to keep it damp. I will appreciate any information you can give me on this subject.

S. C. S.

Answer:—It would require an intimate knowledge of the work to be performed and the conditions prevailing to enable us to advise you as to details of the installation of an apparatus for drying.

The equipment of a dry room or kiln with apparatus for drying presents so many angles that it is quite impossible, in a discussion of ordinary length, to treat the subject intelligently. Each installation, as a rule, requires separate and distinct consideration.

Generally, much better success can be had with a fan system (hot blast) than with a system of any other type. There must be sufficient heat introduced to warm the drier and its contents to the temperature required and sufficient air passed through it to carry away the moisture. It is essential that the amount of moisture to be evaporated in a given time should be known.

The size of the room, 30 x 44 x 8½ ft., is important only as regards volume of air. There is only one good method of moving air by volume and that is by using a fan. The heating surface required can be made up of coils, indirect radiator sections or special heater sections, such as the vento.

* * * *

NOISY BALL CHECK

Could you tell me why a new ball check on the feed pipe of a boiler should be very noisy when the pump is in action?—A. W.

Answer:—The humming of a ball check valve, or chattering of an ordinary flat or mitre seat check valve, is usually experienced when the rate of feed is such that the valve is lifted very slightly from its seat, and kept in a sort of balance by the incoming feed and the pressure from the boiler.

A condition arises when this feed forcing itself past the narrow opening of the valve, causes a vibration which communicates itself to the pipe with a humming or chattering sound.

As a rule a change of speed of the pump will effectually stop this noise, which can be very unpleasant. It has been our experience with ball valves that it is more difficult to keep them from banging than from chattering.

* * * *

TURBINE VIBRATION

What are the principal causes of turbine vibration and what is a simple test for operation?

Answer:—Misalignment and unbalance are frequently the causes of the few cases of vibration reported. Misalignment involves either the turbine and generator or the rotating and stationary elements. In the first instance the misalignment is marked by the heating of the bearings, whipping, extreme working or moving of the shafts and vibration which is extreme under heavy loads although perhaps not noticeable under a light load or no load at all.

If misalignment of the rotating and stationary element exists there is usually rubbing and considerable mechanical noise to indicate it.

Unbalance is the easiest trouble to locate as it produces a steady vibration corresponding to the speed of the machine. It is better at some speeds than at others but at normal speed it remains much the same while the machine is operating.

Other causes of vibration are loosening, warping or failure of parts of the rotor or stator, eccentric or loose coupling, spring shaft, settling of the foundation, floor, piping, or other parts connected with the turbine; strains caused by exhaust piping or steam piping, excessive variation of vacuum, the restriction of oil or cooling water or improper action of the valve gear.

The ordinary test for first class operation is to balance a coin on the bearing bolts. If this will stand satisfactory on edge, the operation is considered good.

* * * *

BOILER FOAMING

What is the difference, if any, between the foaming and priming of a boiler?

Answer:—Priming is simply a boiling over of the water in the boiler, which if it is carried along with the steam to the units in operation sometimes causes considerable damage. Foaming is a frothing of water in the boiler, it is purely a surface effect without any water being lifted from the boiler, it is caused by dirt or greasy water in the boiler.

* * * *

CHIMNEY DRAFT

What produces chimney draft and what does the amount of draft depend on?

Answer:—The draft produced by a chimney is caused by the difference in weight of the gases inside the chimney and the weight of the outside air. The chimney gases have a higher temperature and are lighter, and the lighter

1800 of These *Dunham Radiator Traps* Used on One Big Vacuum Heating Job

NO UPKEEP COSTS IN 12 YEARS!

This same sort of service is available for every kind of industrial plant and office building. It affords the real economy of **lasting service** and an actual **saving of fuel** through improved radiator operation. These make the Dunham Trap the logical selection for replacement of less efficient types and for new installations.

Plant owners, executives, and engineers are invited to write for detailed information about Dunham Heating Service and Heating Specialties.

HEATING SERVICE
(MADE IN CANADA)

Dunham is the original thermostatic disc trap. It is simply constructed, effective, dependable. It has made the low pressure steam heating system practical.

gases rise and the cold air flows in to take their place.

If cold air is heated as it enters a chimney, there will be a continuous current of cold air flowing to replace the heated air that is discharged. Since the draft in a chimney is produced by the difference of weight between the column of heated gases inside of the chimney and the air outside, the draft will be greater with a higher temperature inside or with a tall chimney.

The draft pressure is proportional to the temperature inside (measured from absolute zero), and the velocity is in proportion to the square root of the height of the chimney.

* * * *

RESETTING ECCENTRIC

If the eccentric of an engine has slipped on the shaft and it is imperative to have the engine running as soon as possible without placing the crank on a dead center, how can the eccentric be reset?

Answer:—First, turn the eccentric around on the shaft in the direction of rotation until the admission valve opening is correct for the beginning of a stroke of the piston from that end of the cylinder from which a stroke has been partly completed.

This position of the eccentric can be approximately determined by alternately setting the eccentric forward and opening the throttle valve enough to observe whether steam escapes from an indicator connection or cylinder pet cock in the same end of the cylinder but without moving the piston. Then make a light mark on the shaft to correspond with a mark made on the side of the eccentric, and estimate the angle through which the crank would have to be turned backward to bring the crank on dead center, and set the eccentric the same angle forward of the position previously determined.

U.C.C. of E. Notes

The objects of Toronto Council No. 27, Universal Craftsmen's Council of Engineers, are to educate and elevate engineers whose fraternal affiliations are satisfactory; to bring them into closer contact individually and to comfort and relieve their necessities.

Councils consist of active, associate and honorary members who are Master Masons in good standing.

Active members shall be operating, supervising, or erecting engineers; consulting, mechanical, or electrical engineers, and inspectors or examiners of engineering apparatus, who have been practical engineers.

Associate members shall be men who are directly connected with the engineering profession but who are not qualified for active membership.

On April 23rd Canada Council No. 27 will celebrate its anniversary and a good time is assured to all. Visitors are expected from Fidelity No. 6 of Buffalo, N. Y.; Toronto No. 52 of Toronto; Hamilton No. 60 of Hamilton.

Grand Worthy Chief James M. Patton of Buffalo, P. G. W. C., W. J. Ranton of Rochester, N. Y., and P. G. W. C. Henry C. Senn of Buffalo, N. Y., will aid in the celebration on this occasion.

Mayor C. Alfred Maguire, an honorary member of No. 27, is also expected to answer the roll call on the anniversary night.

Br. A. M. Auchterlonie and his entertainment committee are making great preparations for the anniversary.

Two more applications for membership were received by No. 27 at the last meeting.

Chas. L. Holmes, the smiling Worthy Chief of No. 27, says he would like to see the membership of the Council reach 200 by the end of the year. This and more can be done if every member does his share.

Walter J. Hudson, Rec. Secy.
443 Manning Ave.

An occasional squirt of oil on a bearing is the worst form of lubrication—a feast and famine process, wasteful and inefficient.

Automatic Combustion Control

Recent Developments Allow Entire Plant to be Operated as a Unit to Meet Load

*By F. E. OSWALD

KNOWING of the advancements made during the past few years in the art of burning fuel efficiently, it is hard to believe that only recently the importance of proper automatic combustion control has been recognized as necessary to efficient boiler operation.

The attitude taken toward automatic regulation by the majority of engineers can certainly be appreciated because it is a known fact that until recently it was impossible to obtain a control system that would really operate successfully.

There are possibly more so-called "damper regulators" hanging on the walls of boiler rooms and not working, than any other kind of power plant appliance. An engineer has every reason in the world to be skeptical towards equipment of this kind because possibly at some time he purchased a regulator and found it to be unsatisfactory.

Perfect Control Systems

Times have changed, however, and within the past few years, there has been some real development work done on combustion control systems.

Undoubtedly the most important function of a control system is to save fuel. It is a fact that some regulators are an actual detriment rather than an asset to a boiler plant, so it is of utmost importance to know what to look for when buying one.

In the first place, a regulator should have a gradual movement. That is, the fuel and air supply should at all times be in proportion to the boiler steam pressure or load. A control having just two positions—wide open and tight shut—will possibly hold the steam pressure within a five pound range but it will be at the cost of economical operation.

Secondly, it should be simple in construction with a minimum number of wearing parts. A good regulator should be in as good operating condition after ten years of use as when installed.

Gave Ideal View

Several years ago an engineer of national repute voiced his opinion on what he believed would be an ideal combustion control system. His idea was to have a central or master control actuate auxiliary or secondary controls at various places in the plant, each of the auxiliaries to move in unison with the master. At each auxiliary control there should be a means for adjusting the relation of the movement between the master and auxiliary. In this way an auxiliary control could be placed on each boiler so that individual regulation could be obtained. With this method, therefore, the entire plant would be regulated as a unit to meet the plant load and still there would be a provision for adjusting each boiler so that it would operate at its most efficient rating.

The system outlined above has been worked out and can now be obtained. Almost any combination of methods of control can be had because the better systems manufactured to-day are flexible in application and are sold by companies specializing in this branch of engineering.

Other features to look for when buying a control system are:—

Is the regulator simple in construction or does it have a number of compensating devices and wearings parts?

Will the company selling the equipment give an unquestionable guarantee of satisfaction or money back if you desire to have one?

---

*Sales Manager, Carrick Engineering Co.

C.A.S.E. Notes

The Toronto branch of the C. A. S. E. are issuing a souvenir in commemoration of the 34th annual convention to be held at the Central Technical School, Toronto on June 25, 26, 27, 28.

The souvenir will contain a complete program of the convention and a directory of the branches, secretaries, executives and certificate regulations.

It will be mailed on or before June 9 to all members of the association and to a list of prominent engineers. Copies will also be distributed at the convention to visiting engineers.

* * * *

At a meeting of the executive of Toronto No. 1, C. A. S. E., at the residence of George Fowler, 428 Delaware Ave., Toronto, on April 9th, attended by R. McLaren, president; G. A. Brown, secretary; Ed. Golightly, financial secretary; Geo. J. Soucy, treasurer; J. Quinlan, conductor; G. D. Bly, auditor, and Geo. Fowler, trustee, legislative matters were discussed.

In view of the fact, however, that refreshments and a musical program were in store, the business of the evening was expedited, all present agreeing that Mr. and Mrs. Fowler were splendid hosts.

* * * *

The regular meeting of London No. 30 C. A. S. E., was held Friday evening, April 6, and was well attended.

Grand Conductor, Bro. R. E. Arnup, of Woodstock, was present but Grand Secretary Bro. T. G. Eliss, of Hamilton, who also had been expected, was forced to cancel his visit through unforeseen causes. Bro. Arnup gave an interesting address, and Bros. Lyme and Moll also spoke.

London No. 30 tendered their confidence and support to Bro. G. F. Galloway, who is now Grand President, as a result of the resignation of Grand President Bro. Wright. The London members are sure the association is on the way to greater success.

Jos. H. Ward,
Rec. Secretary,
90 Rectory St.,
London.

* * * *

Kitchener Lodge No. 9 of the C. A. S. E. meets every 2nd and 4th Friday in the month in Moose Hall, corner King and Ontario Sts.

Our regular business meeting was held April 13th, and we had a very good attendance. We held an at-home recently, which also was very successful both in attendance and financially.

Mrs. C. Ott, Miss Merrett and Mr. Rodge Gofton each gave a recitation, also some members of the Waterloo boys' band furnished a few musical selections.

Music for dancing later was provided by Mr. Carl Ott on the Xylophone, accompanied by Mr. Carl Zinkan on the piano.

Bro. Frith of the General Hospital mechanical staff (Toronto) who is a member of No. 9, spent a few days in Kitchener last week and called on a good many brother engineers who were all pleased to see Bro. Frith.

Bro. C. Emmrich, engineer at the Button works, met with an accident recently, and has been laid up for a week with a sprained knee, but we are pleased to see he is now back on duty again.

C. Ott,
202 Breithaupt St.,
Kitchener, Ont.

Announcements

Auto Gear Co., 1175 Bathurst Street, Toronto, have been re-organized and will operate under the name of Toronto Gear Co. at the same address. Henry Winger is the president of the company; W. E. Lear, vice-pres.; E. J. Winger, sec.-treasurer.

The Combustion Engineering Corporation, Ltd., and the Uehling Instrument Company have entered into an agreement whereby Uehling interests in Canada and Newfoundland will be handled exclusively by the Combustion Engineering Corporation, Ltd., with principal offices located in Toronto, Montreal, Winnipeg and Vancouver. The Uehling line includes such equipment as CO_2 recorders draft recorders, combined barometer and vacuum recorders, absolute pressure indicators, etc.

The Montreal committee of the American Society of Mechanical Engineers is doing intensive work in preparation for the spring meeting to be held in Montreal, May 28-31.

Monday, May 28, will be given over to

MAGNOLIA
ANTI-FRICTION METAL

is always uniform in composition and depend[illegible] quickly to rough or scored shafting, makes smooth highly polished contact surfaces and "sets" particles of grit where they cannot cut the journal or appreciably increase friction.

Magnolia Metal melts and pours well, is easily peened and scraped in and is perfectly adapted to a very wide range of speeds and pressures. With the lowest frictional coefficient of any known bearing metal, it runs cool with less lubricant and is excellent protection against hot boxes and melting out where lubrication is neglected.

Sold in ingots and cored bars, the latter to eliminate shrinkage, and pattern and casting costs on small bearings.

Write for test data.

Chemical Manufacturers, Consulting Chemical Engineers
BRANTFORD - - CANADA

a meeting of the council and a business meeting of the society, and in the evening there will be a joint meeting of the councils of The Engineering Institute of Canada and The American Society of Mechanical Engineers. Technical sessions will be held Tuesday morning. Wednesday and Thursday afternoons will be devoted to visits to points of engineering and historical interest in and near Montreal. On Thursday evening there will be a "smoking concert" tendered by the Montreal branch of The Engineering Institute of Canada. A dinner-dance will be held Wednesday evening.

Wayne Oil Tank & Pump Co., have removed their Toronto sales office from 119 Adelaide West, to 165 Dufferin Street. The latter premises were formerly occupied by the Mason & Risch Co., piano manufacturers, the building comprising about 50,000 feet square floor space.

Dodge Manufacturing Co. of Canada are now sales representatives for Chapman ball-bearings, now being made by the Corman Engineering Co., Toronto, and will carry large stocks of the Chapman line in Toronto and Montreal.

Canadian Westinghouse Company has secured the contract for the generators for the Quebec Development Company in connection with the great power project at Lake St. John. The equipment will consist of eight 40,000 horse power water wheel generators. The construction work on the dam is being done by the Nova Scotia Construction Company. In addition to the above equipment the Westinghouse Company sold the Development Company the 15,000 horse power generator for the construction work. This generator will be delivered early in June.

Construction

Yorkton, Sask.—The city plans the construction of a power plant. Estimated cost $100,000.

Port Stanley, Ont.—The Hydro-Electric Power Comm., 190 University Ave., Toronto, plans to build a steam power plant, 1,000,000 h.p. capacity here.

Campbellford, Ont.—The Hydro-Electric Power Comm., 190 University Ave., Toronto, has had preliminary estimates made for developing about 10,000 h. p. at Dam 8, including power house, turbines, generators, switches, transformers, etc., on the Trent River, near here. Estimated cost $1,066,408.

Port Arthur, Ont.—The Hydro-Electric Power Comm., 190 University Ave., Toronto, plans to install a 12,500 h. p. unit in its plant, on the Nipigon River at Cameron Falls, including head 78 ft. vertical turbine directly connected to generator, 120 r. p. m., 10,600 kva., 12,000 volt, 3 phase, 60 cycle; circuit breakers; step up transformers. Estimated cost $1,500,000.

R. H. Cowley, chief inspector for the Board of Education, Toronto, has recommended that a new school be erected south of College Street, near Bathurst, and north of Dundas Street.

Quebec Exhibition Commission is erecting new buildings costing $300,000. The new Industrial Building will cost $125,000, and the Agricultural Building, $175,000. Foundations for the former are now being laid. It is expected the buildings will be completed for the 1924 Fair.

Over ten million dollars is to be spent on rehabilitating the plant of the New Brunswick Power Co. by American interests who have purchased the control of the company's stock. As soon as this work has proceeded to a certain point, steps will be taken to increase not only the company's gas business, but its power business as well.

Engineering & Radio Supplies, Ltd., Orangeville, Ont., have taken over the Cataract Electric Co., and the Industrial Engineering Co. of Canada, and will erect additions to the plant occupied by the Cataract Electric Co. at Cataract, Ont., to increase production from 800 h.p. to 3,000 h.p. R. G. Lee is president of the former company.

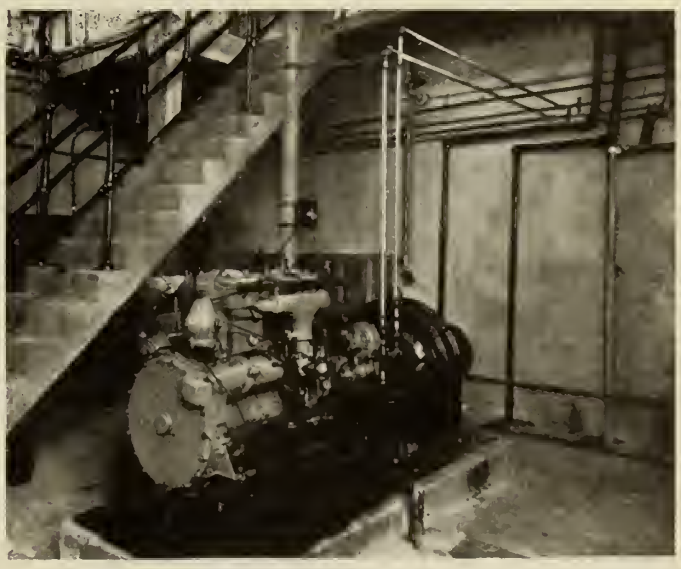
THE ENGINE OF REFINEMENT

High Duty Gasoline Engines for Peak Load and Emergency Generator drives at 1,200 R.P.M.

Assure Dependable Service—at all times.

CENTRAL STATIONS

How do your customers feel about it when power is off? Coal shortages, strikes, transportation delays, line troubles or mechanical break downs may not be your fault. But—you can provide a really dependable standby for about $20.00 a horsepower. Check it against steam at an installation cost of about $210.00 a horse power. No fuel cost when standing by. Check that against maintaining 40 lbs. of steam in banked fires for emergency. In both cases the difference adds to your profits.



24 K. V. A. General Electric generator for emergency in power station at Defiance, Ohio. 4 cylinder Model FC STERLING.

Further particulars on request 50 to 300 h.p. in single units. 600 to 1,500 r.p.m.—centrifugal pump and electric generator speeds.

MADE IN CANADA

DEPENDABLE WRENCHES

Williams' line of "W. & B." Screw Wrenches are strong, sturdy, dependable tools.

Machinists' Knife Handle and "Railroad Special" Wrenches are recommended for the heaviest service; 7 sizes; 6 to 21 inches.

Agricultural Wrenches meet the demand for a good tool at a moderate price. 5 sizes; 6 to 15 inches.

J. H. WILLIAMS & CO., Limited
"The Wrench People"
78 Thorold Road St. Catharines, Ontario

Hospitals MUST NOT risk a boiler shut-down

-other power plants SHOULD NOT!

A modern hospital cannot risk a boiler shutdown in cold weather; **continuous service is a matter of life and death.**

That's why hospitals like nearly all of the large central stations— prefer the

A few of the internationally known hospitals which have the "COPES."

- U. S. Navy Hospital, Wards Island, N. Y.
- Good Samaritan Hospital, Cincinnati, Ohio.
- Rochester Hosp., Power House, Rochester, Minn
- Henry Ford Hospital, Detroit, Mich.
- Crownsville State Hosp., Crownsville, Md.
- Homeopathic State Hosp., Allentown, Pa.
- Mercy Hospital, Chicago, Ill
- Colorado State Hospital, Denver, Colorado.
- Army & Navy General Hosp., Hot Springs, Ark.
- State Insane Hosp., Farnhurst, Del.

COPES System of Boiler Feed Water Regulation

Unfailing reliability. Even when the COPES is neglected, it **mechanically** maintains a safe water level.

The feed rate is changed to meet every change in boiler load, so that there is less furnace forcing. Service records show that the COPES saves 2 per cent. to 8 per cent. of fuel costs.

Our new catalog "D" gives many charts made in actual service, charts which illustrate the **economy** of accurate control. WRITE FOR CATALOG "D"

Makes Short Work of Boiler Scale

In hundreds of plants **BOICO** has been adopted as the one sure clean-boiler insurance. The speed with which it removes the most stubborn scale formations is surprising. Hurts nothing but boiler scale. It's economical, too.

TRY IT FREE—let us send you a sample to convince you. Write us to-day—you've nothing to lose.

Dick's Balata Belt

An unequalled combination of essentials:—

1. Tensile strength.
2. Tractiveness.
3. Pliability.
4. Elasticity.
5. Ability to hold fasteners.
6. Resistance to stretch.
7. Uniformity.
8. Durability.

Don't accept this as a mere statement. Write our nearest Branch for Booklet that shows clearly why this original Balata Belt is the Cost and Power Saver pre-eminent.

Perfect Service Gasket Material

Guaranteed to make a Tight Joint wherever a Permanent Gasket is required.

Place DURABLA in the next joints you make and be insured against a costly shutdown.

DURABLA

TRADE MARK REGISTERED

Strength; Goodness; Quality—these features distinguish durable Gaskets.

DURABLA Sheets can be rolled and unrolled; it never dries out or opens up.

DURABLA Compressed Asbestos Fibre Gasket Material is a guaranteed product that can be used as a standard for all Gasket work. DURABLA Gaskets make tight joints on Steam, Water, Oil, Ammonia and Acids at all temperatures and pressures.

DURABLA is not affected by vibration or condensation. It will not burn out, blow out or pulp at the points. Let us send you a trial sample. Made in stock sizes 36 in. wide x 144 in. long, and 48 in. wide x 144 in. long in thicknesses of 1-64, 1-32, 1-16, 3-32, 1-8.

Orders Filled Promptly.

SECTIONAL COVERINGS

Retains its
Coal-Saving
Qualities

It Never
Deteriorates

DON'T be misled! Many pipe coverings made in the past few years show up well under efficiency tests but in practice fail to stand up. Durable qualities are lacking. Cases are on record where such coverings have been shaken to pieces within a year.

You need pipe and boiler covering that holds its heat-conserving qualities for years. That is the only kind that pays. You want K. & M. "Featherweight" 85% Magnesia Pipe and Boiler Covering.

The same heat saving efficiency, the same saving of coal is registered, whether 85% Magnesia coverings have been on steam pipes for a week, a month, a year or a quarter of a century.

Let us explain more fully 85% Magnesia.

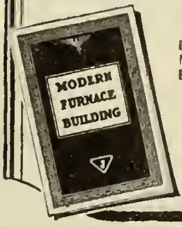
PLIBRICO
JOINTLESS
FURNACE LINING

The beginning of furnace economy

This 50-page book FREE



WHEN you have opened your first container of Plibrico Furnace Lining then—and not until then—you have started on the direct road to economical furnace operation.

Plibrico is a plastic lining that is installed with mallet and trowel. When baked, it forms a jointless lining that is airtight, gastight, resistant to temperatures to 3100 deg., and that outlasts ordinary fire-brick linings two to four times. Because of its putty-like form, Plibrico is ideal for baffles, arches and other special shapes.

Plibrico is delivered only in steel containers of distinctive appearance as shown above and below.

DISTRIBUTED BY: Beveridge Supply Co., Ltd., Montreal; Shell Bar Boico Supply Co., Ltd., Toronto; Evans, Coleman & Evans, Vancouver, B.C.; Winnipeg Supply and Fuel Co., Winnipeg; Gorman's Ltd., Calgary, Alta.

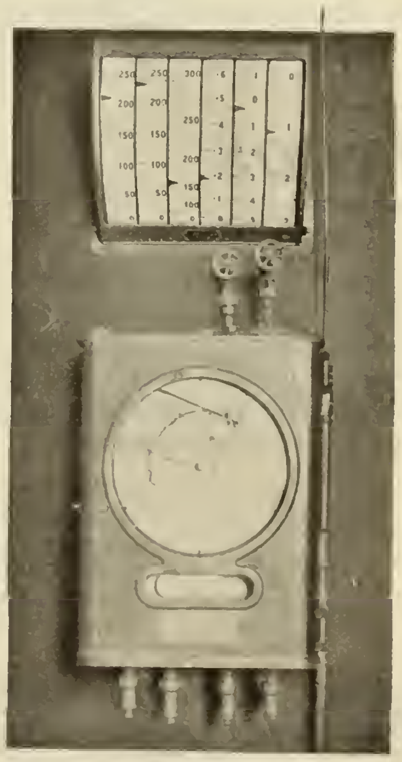
JOINTLESS FIRE BRICK CO
1142 Clay St., CHICAGO, ILL.

How Much Coal Are You Wasting?

Blindfolding yourself to the fact that your boiler room is different, because you can see no pipe line leaks, or the water alarms don't blow very often—doesn't help to pay for the needless fuel waste caused by the invisible losses within the boiler furnaces.

Get at the REAL FACTS and at the same time give your men a positive and simple guide that will enable them to keep the plant at top notch efficiency—by installing the

BAILEY BOILER PANEL



The Bailey Boiler Panel is a combination of the Bailey Multi-Pointer Gage and Bailey Boiler Meter.

It shows, almost immediately, the effect of improper furnace adjustment and enables the men to make the necessary correction before a large amount of preventable fuel waste has taken place. Good work on the part of the men is shown up by the charts as well as any inattention. The engineer can check the efficiency of his men as well as that of the individual boiler.

Let us send you fully descriptive Bulletins.

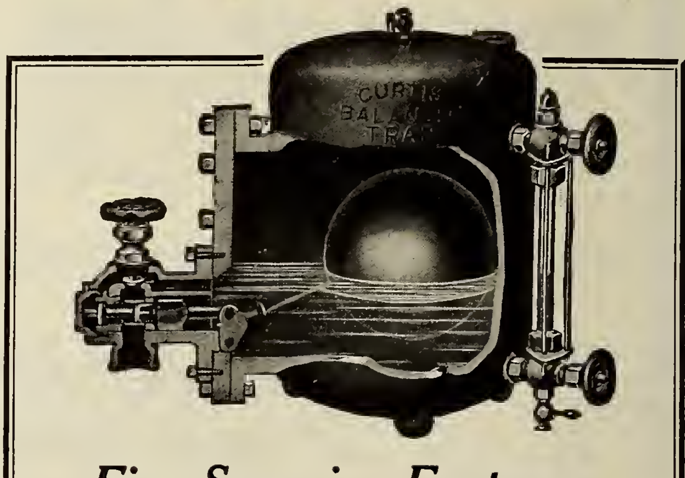
Curtis Engineering Specialties



Five Superior Features of the Curtis Trap

1. A perfectly balanced valve.
2. An absolutely frictionless valve.
3. The valve can be removed without breaking a joint, starting a gasket, or taking out a bolt.
4. The valve being frictionless and balanced, the whole power of the float is available for opening and closing the valve.
5. Each trap will operate perfectly on high and low pressures.

Send for descriptive circular of this trap.

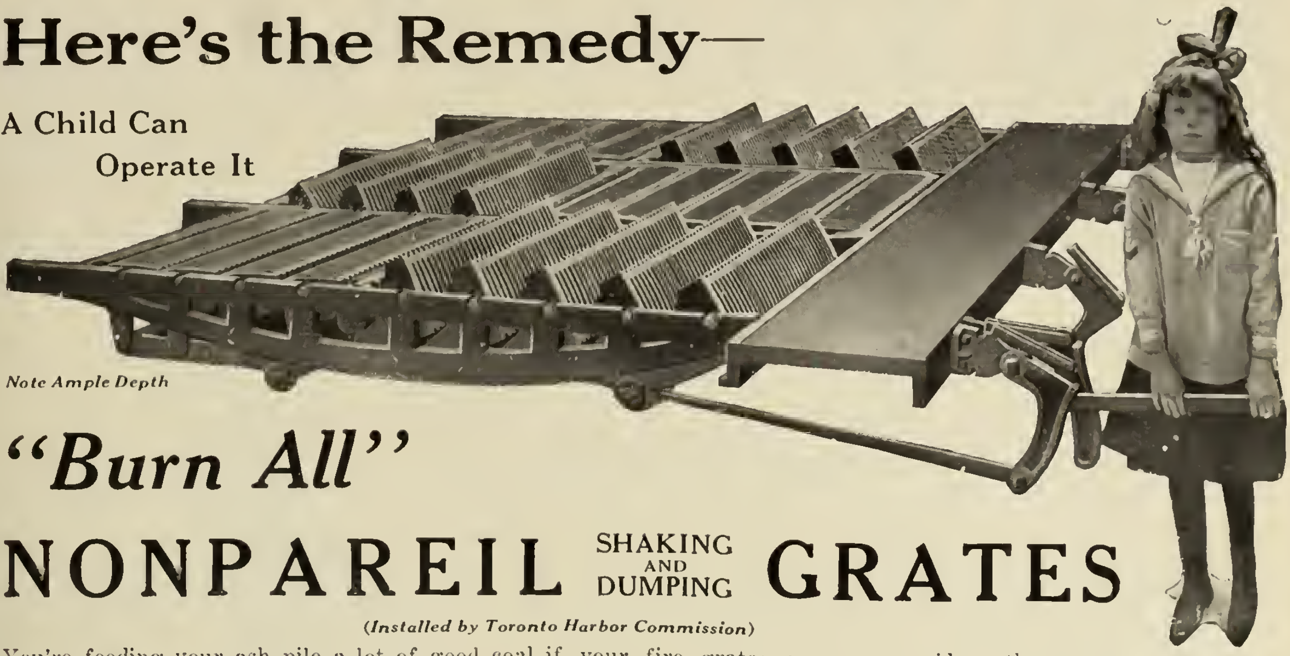
Got Any Fuel Troubles?

Here's the Remedy—



"Burn All"

NONPAREIL SHAKING AND DUMPING GRATES

(Installed by Toronto Harbor Commission)

You're feeding your ash pile a lot of good coal if your fire grates are not providing the proper proportion of air to get complete combustion.

The 65% air space and 95% underdraft that is a feature of NONPAREIL GRATES under normal conditions means that you are getting full value for every dollar you spend in fuel.

That's the way some of the largest Canadian concerns figured when they decided to instal

NONPAREILS

after putting them to the test. Not only that, but they found out that they could get maximum heat value even out of cheaper grades of fuel. Now they're saving both ways! Why not investigate?

FIRE BRICK WORK

Our Specialty

Let "Safety-First" Sexton handle your fire brick work, building-in boilers and general repairs. Only the best high tension fire cement is used. Sexton has gained a reputation for doing the work with rare efficiency. His work lasts longest and many of the largest plants are ready to back up this statement.

Call in Sexton for renewals and repairs for all kinds of Shaking and Dumping grates for all sizes of boilers.

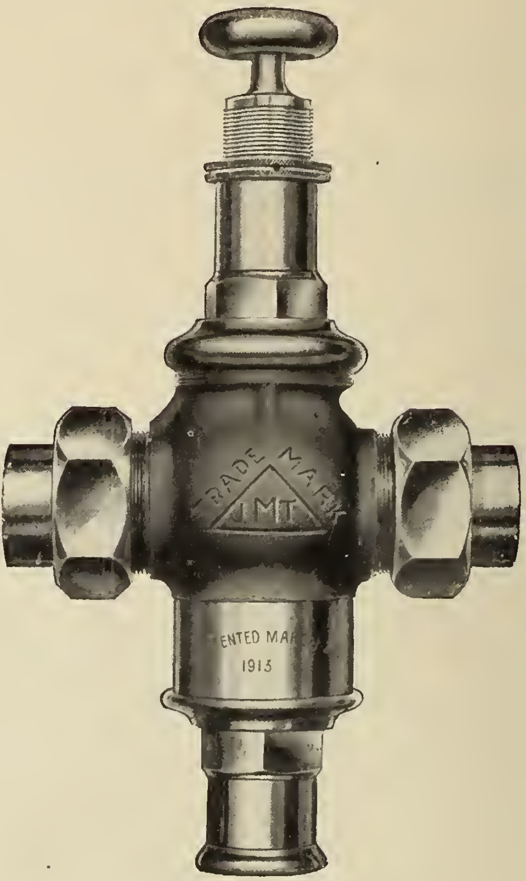
MORRISON

STEAM GOODS

Steam Fan Regulators



THE application of a close study into the requirements of steam specialties during our fifty years' experience is reflected in the widespread popularity of Morrison Steam Goods.

Exacting engineers appreciate the fact that superior quality, workmanship and design ensures dependability at all times, even under the shocks of constantly changing conditions.

The Regulator here shown may be depended upon to maintain a uniform boiler pressure by varying the speed of the Fan Engine according to the requirements of the plant. They are also used for controlling steam jet blowers.

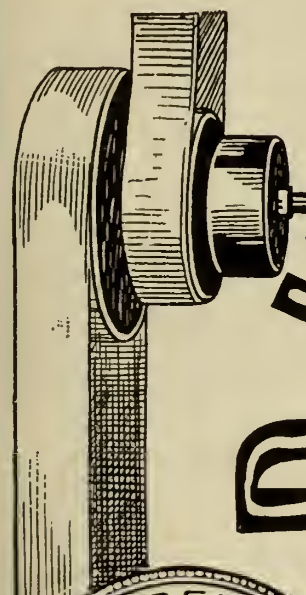
D. K. McLAREN'S

Genuine British-
-Oak Tanned
Leather Belting



EVERY time a belt needs repairing during working hours a tremendous waste of time is incurred—men are idle, machines are idle, production is retarded.

All belts require repairing at some itme. But the belt that requires the least amount of repairing is the most valuable. In the course of a year a good quality belt will save many hours of production time.

D. K. McLaren's Leather Belting is of **good quality**—the kind that can be depended upon to require the least amount of repairing. It gets its good quality from the fact that it is made from the choicest part of carefully selected hides (the best part of the hides for belting the backs) and furthermore each piece of leather is then treated with the famous **British Oak Tanning Process** by expert men of long experience. Specify D. K. McLaren's Belting on your order and you will be assured of less belt breakage, less belt slippage and all-round belting satisfaction.

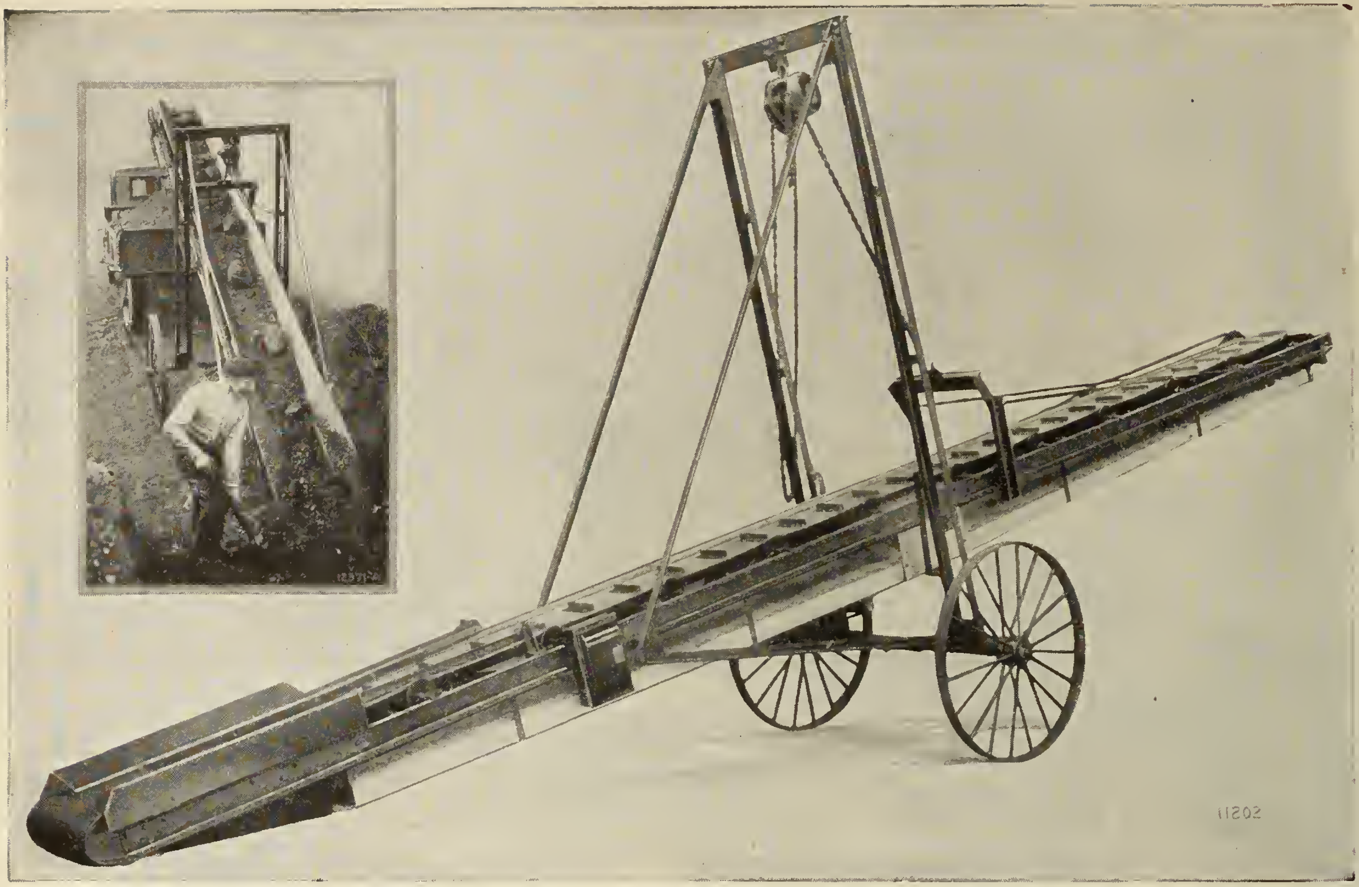
Manitoba's Daily Heating "Log"
Corrosion Problems in Power Plants



THE "CUB"—A LINK-BELT LOADER—$790.00

FEATURES

- Simplicity of design.
- Length of conveyor, 21 ft.
- Substantial construction—weighs about twice as much as some machines of this type.
- 18" wide belt, giving large carrying capacity.
- Belt guaranteed against cutting or fraying.
- Wide loading hopper at foot of conveyor is hinged—easily and quickly opened.
- Requires little power—2 H.P. motor, 2 or 3 phase, 60 cycle, A. C.

HERE'S a thousand-dollar Link-Belt Portable Belt Conveyor at our new low price—$790.00. It is one of our standard types, built to the high Link-Belt standard. It is guaranteed.

Increased production, due to our large volume of sales, has made this low price possible.

Even if you load only a small quantity of material—at intervals—can you afford to pass up an opportunity like this ? Fill out and return the coupon.

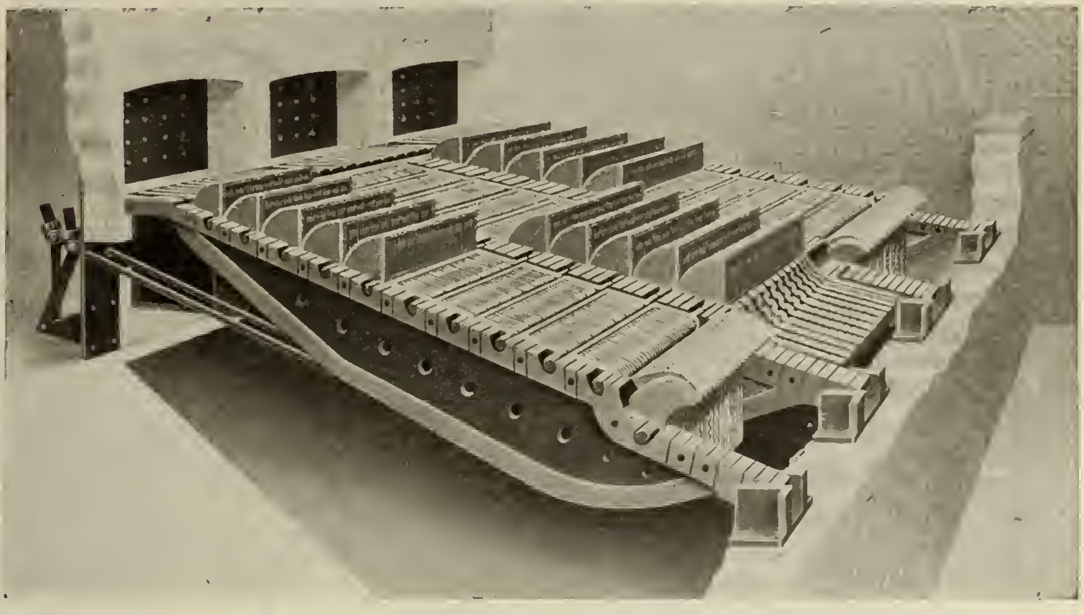
LINK-BELT



THE FILES STOKER

Pays for Itself in One Year

Below is a copy of one of the many letters we have received, telling of the efficiency and economy of the Files Hand-Operated Stoker

Re FILES HAND STOKERS.

Gentlemen:—

Frequently we receive letters from manufacturers, asking for information and our experience with the "Files Hand Stokers"—the most economical and efficient system of burning coal with the utmost conservation of labor.

As these inquiries are becoming more and more frequent, our better plan will be to furnish you with a letter to pass on, outlining our experience and satisfaction.

In September, 1920, we placed an order with you for two 150 H.P. Tubular Boilers, specifying our desire to have them equipped with "Files Hand Stokers." This we did on the recommendation of our United States Engineering Department, who had installed "Files Hand Stokers" in some seventeen plants, finding in them a decided saving and advantage over flat or shaking grates.

Speaking for ourselves, we have found them most satisfactory and economical, particularly so in regard to the elimination of smoke, rapid disposal of ash and clinker, thorough cleaning of fires without disturbing the active fire, and in maintaining an even bed of fuel.

We are able to keep a clean fire at all times; we have no cleaning period, for with the "Files Hand Stoker" the grate can be cleaned at peak load. It is only a matter of working one rod on each section, which can be done in less than two minutes.

The better the coal the better the result, but almost any kind of coal that will burn free can be used. With good coal, however, it is an easy matter to procure 150% boiler rating, which in reality is 12½ lbs. evaporation per pound of coal. Generally speaking, evaporation is around 7 or 8 lbs., and often as low as 5 or 6 lbs.

Our Files Hand Stokers have now been installed about two years, during which time they have paid for themselves twice over if we consider the saving in fuel.

And what we have done and are doing with them others can do.

We know they effect a saving; we know they are a convenience; they have proved satisfactory in every particular, and we have no hesitation in recommending them.

Yours very truly,

THE MERIDEN BRITANNIA CO., LIMITED.

Why not Profit by others Experience?

"Vigilant" Safety Water Column

LUNKENHEIMER
"Vigilant" Safety Water Columns

Automatically sound an alarm when the water in the boiler reaches the high or low water level.

They not only aid in the prevention of accidents, but also in the maintenance of a uniform water level which is essential for the economic operation of the boiler.

For working pressures up to 250 pounds and obtainable in sizes suitable for any make or type of boiler.

LUNKENHEIMER WATER GAUGES AND GAUGE COCKS are also very important factors in the safe operation of a boiler. The extensive line permits of a selection particularly adapted for individual requirements.

Complete data pertaining to the entire line of Lunkenheimer Boiler Mountings is given in Catalog 58-DC, a copy of which will be sent upon request.

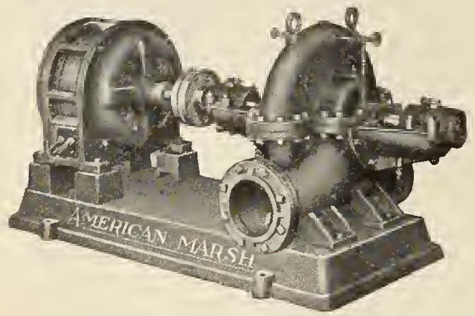
AMERICAN-MARSH PUMPS

Centrifugal and Direct Acting



Designed for use in power plants where absolute reliability and high efficiency are essential. For over thirty-five years American-Marsh Pumps have been recognized as standard throughout the Dominion. There are over 160,000 in successful operation.

The sturdy rugged construction and heavy cast bronze fittings insure long life and a minimum repair expense.

American-Marsh Centrifugal Pumps are built with the same painstaking care that characterizes the construction of the direct acting line.

The Line includes :

- Boiler Feed Pumps
- Air Compressors
- Deep Well Engines
- Centrifugal Pumps
- Jet Condensers
- Vacuum Pumps
- Condensation Pumps
- Sump Pumps

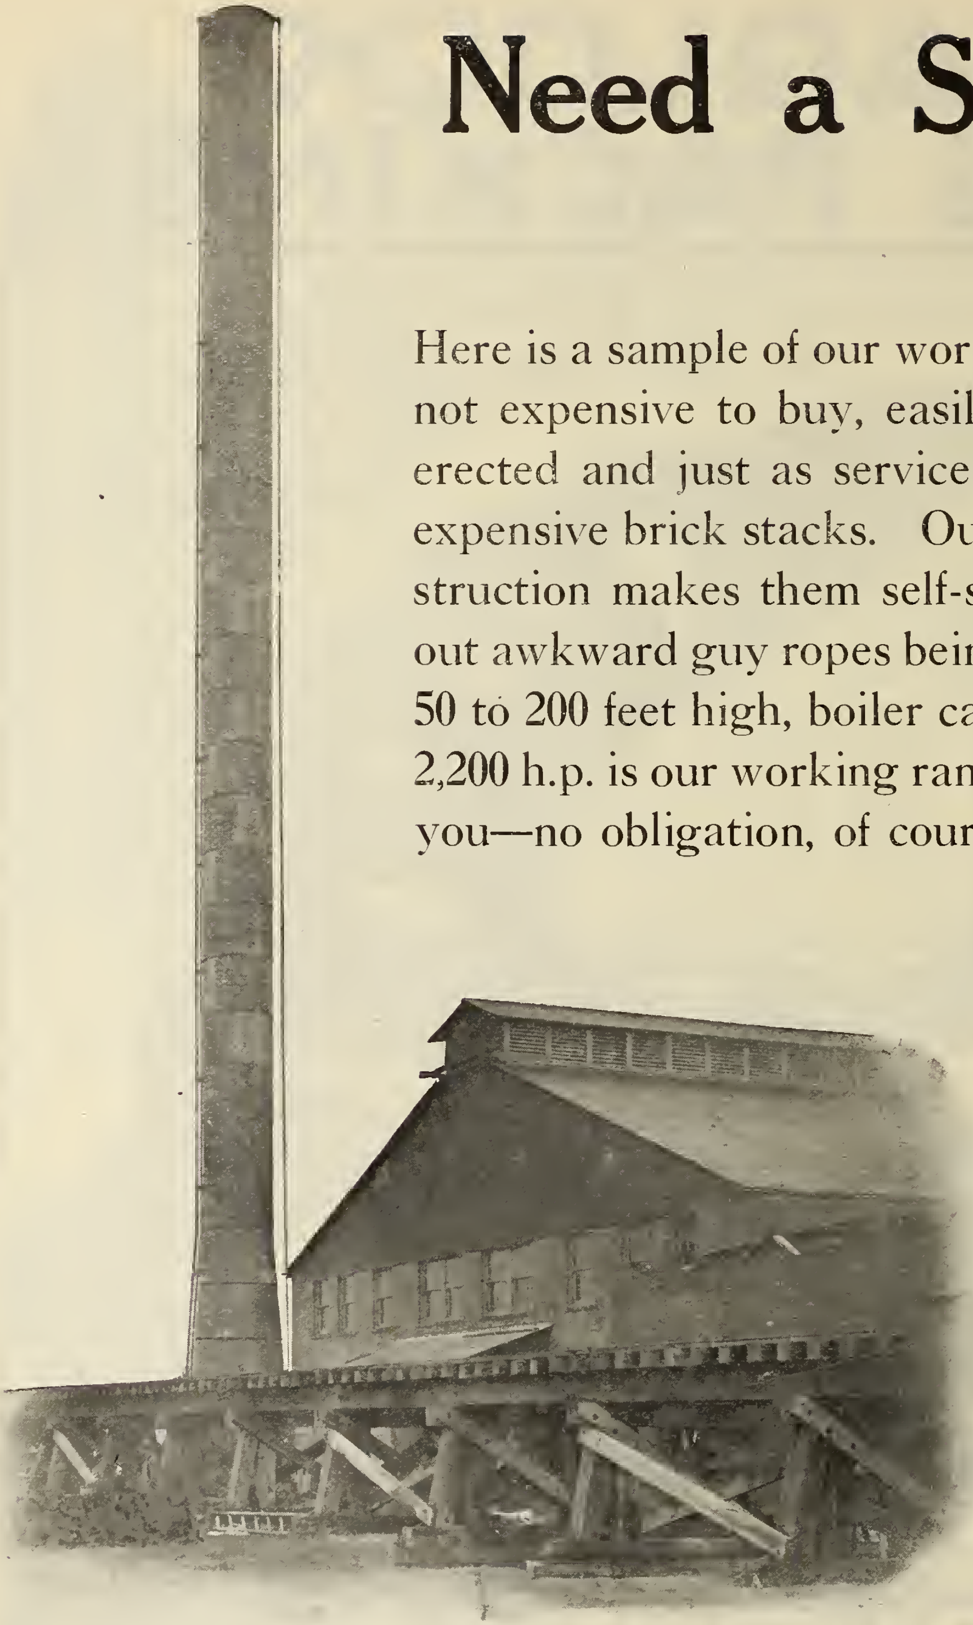
Need a Stack?

Here is a sample of our work—a Steel Stack, not expensive to buy, easily and promptly erected and just as serviceable as the very expensive brick stacks. Our flare base construction makes them self-supporting without awkward guy ropes being needed. From 50 to 200 feet high, boiler capacity 20 h.p. to 2,200 h.p. is our working range. Let us quote you—no obligation, of course.



A self supporting steel stack, 140 feet high, 6 feet 6 inches diameter, erected by us for Pilkington Bros., Limited, Plate Glass Works, Thorold, Ont.

Are You Getting Satisfactory Service From the Hydraulic Packing You are Using ?

If not, try

SQUARE
PALCO
PLAITED PACKING

Its Long Service Quality Will Surprise You

Palco is made of a cotton having a far higher tensile strength than flax, and is an ideal packing for centrifugal pumps.

Because of its thorough lubrication it withstands friction, and does not wear and score the rods as other packings are apt to do.

Palco does not swell and so bind as to prevent reciprocating pumps from developing their full efficiency.

Palco will give most satisfactory service under low pressure saturated steam.

Let us send you a working sample to test under your own conditions —no charge. Advise size desired.

$5000. Worth of Goods RUINED!
—A Loss that Could Have Been Prevented by

Columbia

Recording Thermometers

With Time PUNCH

The TIME PUNCH on Columbia Recording Thermometers practically compels the heat tender to maintain an even temperature in heat-treat processes, where wide variations may mean spoilage. For he knows if he doesn't "ring up" at regular intervals that the absence of the punch holes on the chart will tell that he was delinquent.

Side by side with the Time Punch holes on the day-and-night chart runs the line that indicates the temperature. Let that line deviate too much from its proper course and you have positive evidence of deliberate neglect.

Under these conditions you may depend upon it that your operator will exercise more than usual care. The Time Punch and the temperature line combined protect you against loss in heat-treat processes as you have never been protected before.

The Time Punch is an exclusive feature found only on Columbia Recording Thermometers, Gauges and Tachometers.

Write to-day for our interesting booklet H-33.

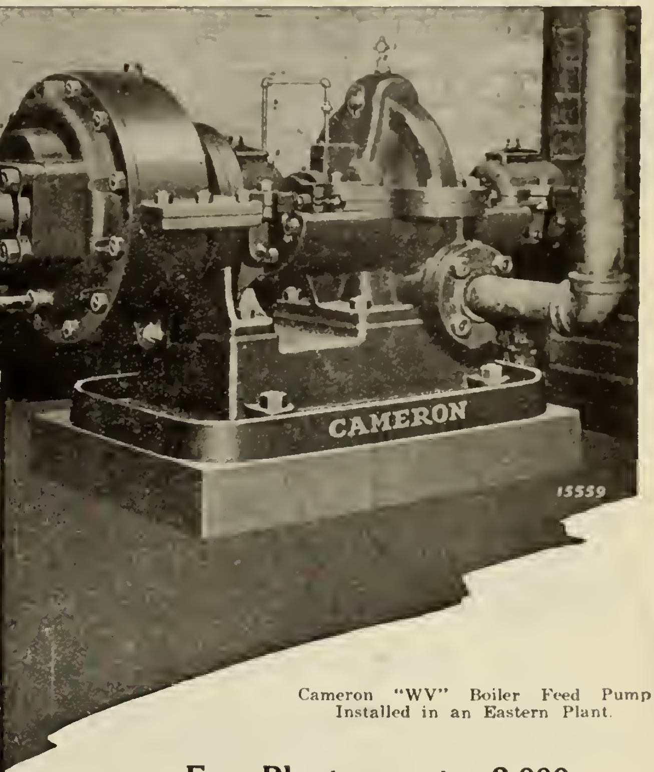
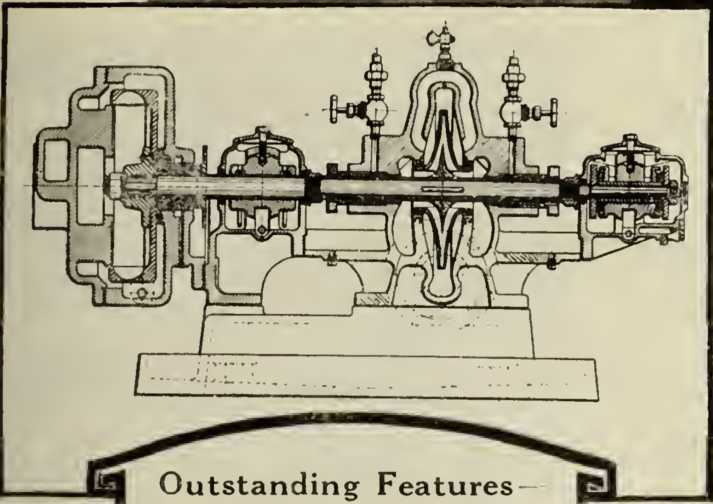
The Boiler Feeder you have been waiting for



Cameron "WV" Boiler Feed Pump Installed in an Eastern Plant.



Outstanding Features—

- No couplings—No valves
- Only two bearings
- Only one gland on the turbine
- Reduced floor space
- Horizontally split casings
- Impeller and rotor on same shaft
- No pipe vibration
- Only one moving part
- No high pressure stuffing boxes

For Plants up to 2,000 Boiler Horsepower 150 pounds pressure

The new Cameron single-stage, turbine-driven Centrifugal Boiler Feed Pump is designed for boiler plants having up to 2,000 boiler horsepower and using steam pressures of 150 pounds or less.

The outstanding feature of this Pump is its simplicity. The single-stage impeller and turbine rotor are mounted on the same shaft. The absence of a coupling and the compact design results in a remarkably large capacity per unit of floor space required.

With this unit the small boiler plant can now secure the outstanding advantages of a Centrifugal Boiler Feed Pump.

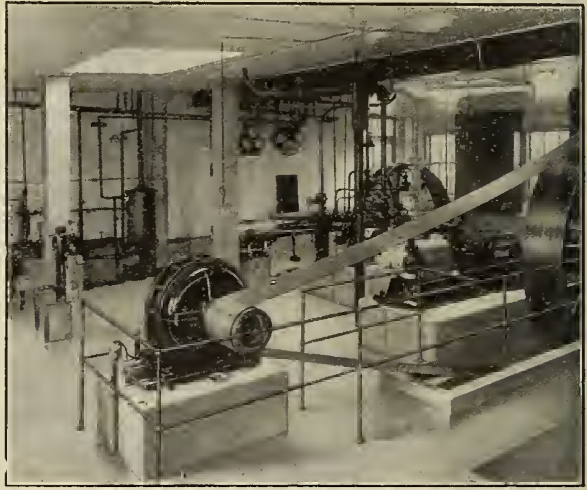
REFRIGERATING AND
ICE MAKING MACHINERY

For Refrigerating and Ice Plants
Large and Small.

Mechanical refrigeration scientifically applied yields increased returns to the user.

Linde Refrigerating and Ice Making Machinery offer every improvement and convenience. Our new vertical enclosed type machines are designed for plants from 1 to 30 tons. Then for demands calling for loads up to 300 tons, our horizontal frame type is guaranteed to give better service than any other equipment on the market.



This 100-ton plant was designed by our engineers. These men are at your service. Designs, specifications and estimates upon request.

Nonpareil Corkboard in process of erection for the John J. Woodside Storage Company, Atlanta, Ga.

Yours is a Special Case.

Every cold storage room or building is an individual problem in insulation. *Your* conditions must be studied, *your* requirements analyzed and *your* insulation planned to suit *your* needs. Rule-of-thumb methods like "So many inches for such and such a temperature," will not assure *you* efficient and economical insulation for your rooms.

Most users of refrigeration recognize Nonpareil Corkboard as the standard cold storage insulation. But thousands of them know that the efficiency of their rooms is due as much to the helpful suggestions, the expert knowledge and the skilled workmanship that constitute Nonpareil Service as to the high quality of the material itself. The resources of an experienced organization applied to your individual case are what assure you the results you expect from your insulation.

There may be little *apparent* difference in materials, but remember this: Insulation should include a service as well as a material. Consider the value to you of this Company's years of experience in planning and installing insulation, in studying the mistakes that have been made, and in endless research for better methods. This experience and Nonpareil Corkboard are your best assurance that your insulation will be adequate for your requirements, efficient, economical and permanent.

Have you rooms to be insulated? It will not obligate you in the least to consult with our Engineering Department. Ask for a sample and a copy of "Small Cold Storage Rooms," sent free on request.

"Multiple retort" in everything but price—

BEFORE the *"lateral retort"* principle was developed there was no such thing as a strictly *underfed* side-cleaning stoker. Consequently, the many advantages of underfeeding coal were confined to more expensive stokers of the high-duty multiple retort type.

Now, as a result of the revolutionary *"lateral retort"* principle, the advantages of the multiple retort stoker —high capacity and efficiency—are combined with the advantages of the side-cleaning stoker—lower first cost, reduced installation cost, and adaptability to old boilers.

The *"Lateral Retort"* Stoker is not claimed to be a substitute for multiple retort stokers – *but*—it *does* bring the advantages of multiple retort stoking to the plant that otherwise would install an inferior stoker, thus providing multiple retort efficiency while effecting a marked saving in initial and installation cost.

The illustration above shows how the truly underfeed effect is accomplished. The coal follows the path of the arrows. It is first underfed along the line of the main arrow into the central retort by means of a main ram. It is then underfed—always underfed—into the *"lateral retorts"* by means of an auxiliary steam cylinder which operates lateral pusher rods.

There is only one simple moving unit for distributing fuel in five or more *"lateral retorts"* and, since this feeding mechanism is controlled independently of the main fuel feed, ideal distribution is possible under all conditions.

A trench 6 to 18 inches below the floor line is sufficient excavation for ash pits. This reduces installation cost and makes the stoker adaptable to boilers already in service. The many good points of this stoker are covered in greater detail by a new bulletin. Where shall we send it?

The "Lateral Retort"
Trade Mark
Stoker

Advantages of the *"Lateral Retort"* Principle

Coal is underfed throughout—not overfed on to side grates. This is the only truly *underfed* side-cleaning stoker.

One simple moving unit for five or more retorts—The feeding mechanism of the *"lateral retorts"* is controlled independently of main feed, permitting ideal fuel distribution under all conditions.

Simplest cleaning mechanism—a perfectly balanced dump plate easily operated by hand.

No need for basement ash pits—A trench 6 to 18 inches below the floor line is sufficient excavation for ash pits. This greatly reduces installation cost and makes the stoker adaptable to boilers already in service.

Plate tuyeres — reduce siftings and lower replacement cost.

High air cooled front and rear tuyere blocks—keep fire and clinkers away from front wall and bridge wall, reducing furnace maintenance.

How Much Coal Are You Wasting?

Blindfolding yourself to the fact that your boiler room is different, because you can see no pipe line leaks, or the water alarms don't blow very often—doesn't help to pay for the needless fuel waste caused by the invisible losses within the boiler furnaces.

Get at the REAL FACTS and at the same time give your men a positive and simple guide that will enable them to keep the plant at top notch efficiency—by installing the

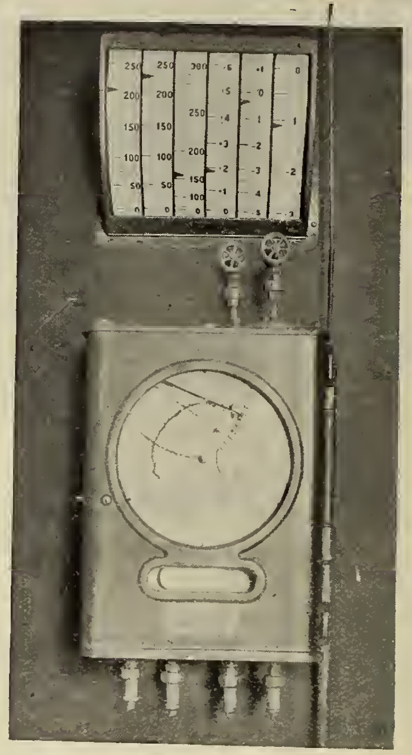
BAILEY BOILER PANEL

The Bailey Boiler Panel is a combination of the Bailey Multi-Pointer Gage and Bailey Boiler Meter.

It shows, almost immediately, the effect of improper furnace adjustment and enables the men to make the necessary correction before a large amount of preventable fuel waste has taken place. Good work on the part of the men is shown up by the charts as well as any inattention. The engineer can check the efficiency of his men as well as that of the individual boiler.

Let us send you fully descriptive Bulletins.

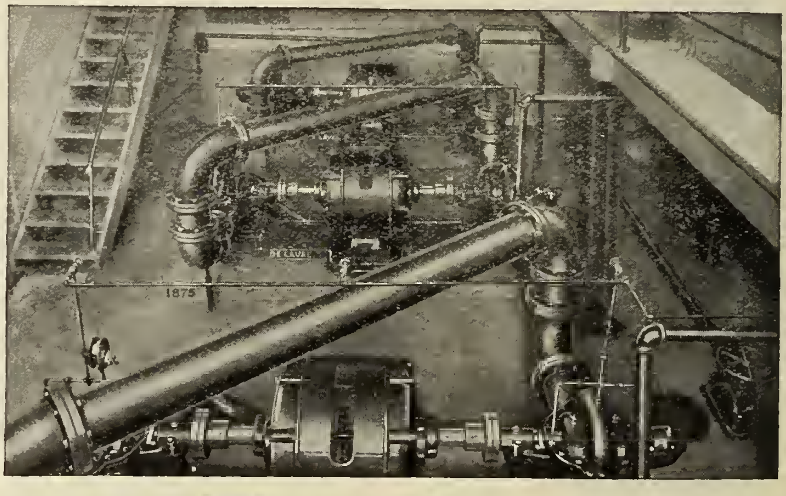
BAILEY METER COMPANY Limited
177 DELORIMIER AVE. - MONTREAL, QUE.



De Laval Motor Driven Pumps
For Belleville, Ontario

THE City of Belleville, Ont., has installed three De Laval motor driven centrifugal pumps for its water supply, each consisting of two De Laval single stage pumps, on one base plate, with a driving motor in between. One unit, with 8-in. pumps, delivers 1,870 gal. per min. against 200 ft. head at 1,740 r.p.m., one with 6-in. pumps delivers 1,300 gal. per min., while another with 6-in. pumps delivers 960 gal. per min., each against 285 ft., at 1,740 r.p.m.

The pump casings are split horizontally, the top half being removable without disturbing piping. All internal parts are then accessible, and can be taken out after removing the bearing caps. Parts are made to limit gages on an interchangeable basis, and parts subject to eventual wear, such as wearing rings and shaft sleeves, can readily be removed and replaced by ordinary unskilled workmen. The De Laval labyrinth wearing ring permits of large running clearances and its life is much longer than that of a flat ring.



Where electric power is purchased for driving pumps, the user can easily calculate how much more he can afford to pay for an efficient pump than for an inefficient pump. In making this calculation, he should consider, however, not only the initial guaranteed efficiency, but also durability, that is, whether the construction of the pump is such that the efficiency will be maintained in service and can easily be restored, when necessary, by replacing parts subject to wear.

The efficiency of every De Laval unit is guaranteed, and the guarantee is corroborated by a test at the works before shipment. Ask for special catalog B-100.

Waste Has No Hiding Place at the Rockford, Ill. Water Works

Waste can't sneak into the boiler plant of the Rockford, Ill., Water Works unannounced.

The records from the Foxboro Instrument Board, illustrated above, and three Foxboro 3-pen Draft Recorders not shown, provide protection against the many lurking robbers of the coal pile.

The clean, accurate, continuous records of CO2 content in flue gases, flue gas temperature, feed water temperature and draft in the last pass, above the fire, and in the wind box, make possible careful development and constant maintenance of wasteless operating standards.

Foxboro Recorders are designed and built by engineers who know power plant conditions and realize the importance of permanent accuracy in the instruments which produce these vital records.

Every Foxboro Recorder must pass tests which prove it fully capable of performing the service expected of it as "The Compass of Industry."

For full information, write for Bulletins CF104-1 and 114.

How This Instrument Board Helps.

This board contains one Foxboro-Heath CO2 Recorder, three Foxboro Recording Thermometers for flue gas temperatures and one Foxboro Recording Thermometer for feed water temperature.

Roughly:

- **Every 1% increase in CO2 (between 11 per cent. and 14 per cent.) means 1 per cent. saving in fuel.**
- **Every 25°F reduction in flue gas temperature means 1 per cent. saving in fuel.**
- **Every 10°F increase in feed water temperature means 1 per cent. saving in fuel.**

Foxboro records help to keep conditions close to the standards set for maximum economy; minimum waste.

"CSC" Self-Oiling engines are made in single and double cylinder types of from 2 to 120 H.P.

This Sturdy Engine Gives Unfailing Power for Months Without Attention

It is hard to realize that any steam engine could endure day-and-night operation—seven days a week—for ten, fifteen and even twenty years. Yet such instances are not uncommon in the case of "CSC" Self-Oiling Engines.

These remarkable power units are designed especially for the operation of blower fans, mechanical draft apparatus, lighting plants and other uses where stops are days or weeks apart. Ample lubrication under all conditions, rugged construction and high efficiency make the "CSC" Engine one of those rare pieces of equipment that you can install and then almost forget.

Write for details of construction and startling testimonials of its wonderful performance.

In Service More Than Six Years—Not Even Re-packed

Back in 1916, the Unity Cotton Mills, La Grange, Ga., put 5 Yarway Seatless Blow-off Valves on their boilers. In December 1922—more than six years later—Mr. James Newsom, manager and superintendent, wrote that the valves............"have not been re-packed nor repaired since we bought and installed them, and have been and are still giving entire satisfaction. They are the best blow-off valves that we have found."

The experience of this well-known Southern mill has been duplicated by hundreds of other users in all parts of the country. The "no-seat-to-leak" construction of the Yarway Seatless Blow-Off Valve makes possible its many records of six, eight and ten years' service without repairs.

The Yarway Seatless and the Yarway Double-Tightening Valves in tandem form the ideal combination for blow-off service, complying with laws of every state.

Both valves are fully described in Booklet B-410—free at your request.

POWER HOUSE

ESTABLISHED 1907 *Toronto, May 5th, 1923* A SEMI-MONTHLY NEWSPAPER

Central Heating of Manitoba's Parliament Building

Daily "Log" Kept of Water of Condensation From Which Statement of Total Cost of Operation is Prepared for Minister of Public Works Each Month—Novel Color Scheme Adopted in Piping Throughout System

BY GEO. R. ARCHDEACON, A.M.I.E.E.

ALTHOUGH Winnipeg, the "Gateway of the West," possesses many things that its citizens are proud of, there is nothing in which their pride is so well justified as the Manitoba Parliament Building.

The plans were selected in a competition open to all architects practising in the British Empire, the successful design being that of Frank Worthington Simon, F. R. I. B. A.

The building is constructed of Tyndall stone and its general outline resembles the letter "H," each arm of the structure being 300 feet long.

The final cost was approximately $8,000,000 and it is therefore apparent that nothing was neglected to make it comparable with the historic public buildings of Europe.

The engineering service is naturally in keeping with the size of the building itself.

The power house is situated about 2,000 ft. from the main building, and it may be safely said that the equipment rivals that installed in any other central heating plant in Canada because it typifies the ideal heating layout in as much as the power house is in the centre of the system of distribution.

System of Tunnels

A complete system of reinforced concrete tunnels connects the power house with the various buildings as follows:

Parliament Bdg. 2,000 ft., 6 ft. 9 in. x 8 ft. 0 in.
Law Courts, 300 ft., 6 ft. 0 in. x 6 ft. 0 in.
Old Law Courts, 500 ft., Conduit.
Provincial Jail, 500 ft., Conduit.
Electrical Bdg. 900 ft., Conduit.
Science Bdg., 900 ft. Conduit.
Land Titles Bdg. 70 ft., 5 ft. 0 in. x 5 ft. 0 in.
Greenhouse 100 ft., 4 ft. 0 in. x 4 ft. 0 in.

> **If you can reach out and touch the door that will open on your success, turn the knob and walk in. Never admit that the threshold of success is new to you, for if it should be, over-anxiety will lock the door. Do not push with all your soul, for when you do, you show your fear and doubt as to whether the door will yield, and it has never opened yet in the power plant field to the man who doubted his own ability.**

The power house itself, viewed from the exterior, has the appearance of an old university chapel and its location in a wide court yard, surrounded by the Manitoba University Buildings completes the illusion.

The boiler room is well lighted and lofty, the coal being taken in by a 10 ton automatic weighing machine, which at the same time automatically punches a ticket with the correct weight and date similarly to the cash register of retail store fame.

This machine was designed and made by the Canadian Fairbanks-Morse Co.

After being weighed, the coal passes on to a crusher. Here it is crushed into small pieces, by a machine operated by a 10 h.p. Westinghouse induction motor. From this crusher, the coal drops into a rotary filler, with 6 openings or outlets. Each outlet as it rotates synchronizes with a bucket moving on a belt, the contents of the rotary filler being fed to the bucket without spillage. This ensures the actual amount of fuel weighed arriving safely in the boiler.

This bucket conveyor has a capacity of 20 tons per hour, and elevates the coal to a bunker with a capacity of 700 tons, located over the tops of the boilers.

Ash Weighed Daily

This conveyor is also made to serve the purpose of an ash conveyor, and in turn handles the ashes, and conveys them to a 40 ton ash bunker above the platform scales, the ash is there weighed and a daily record made to check against the weight of coal taken into the boilers.

There are 5, 250 h.p. B. & W. boilers 4 in. tubes. Drums 36 in. x 21 ft. 6 in. Working pressure 150 lbs. equipped with B. & W. chain grate stokers, with in addition Copes automatic boiler feed regulators connected to each boiler.

Uehling draught gauges are installed throughout. There is a CO_2 recorder on each boiler to permit the firemen to observe conditions whilst in the chief's office a CO_2 recorder from the main flue is installed which permits the use of a low chimney stack.

A set of B. & W. economisers are connected to each boiler, and the inlet and outlet temperature is carefully observed by means of electrical pyrometers made by Schaeffer & Budenburg.

There is also an electrical generating station, supplied, it is claimed, with high tension electric power at approximately half of one cent per K. W. Hr., the equipment consisting of:—

2—200 K. W. motor generator sets, each set comprising a 2,200 volt Synchronous motor, direct coupled to a 22V D. C. dynamo operating at 900 Revs.

Switchboard of Marble

The switchboard is 10 ft. long, and 7 ft. high, of unpolished black marble, and comprises the usual control panels for the branch circuits, and also for the high tension and low tension sides of the motor-generator.

There are 2 Ingersoll-Rand Automatic air compressors, direct-connected to 2, 10 h.p. induction motors.

When the pressure in the air tank reservoir falls below a certain value, the air compressor automatically starts up.

There is a 40 h.p. single cylinder steam engine so installed, as a stand by for the induced draught system, that the drive from the electric motor to the fan is accomplished by running the belt from the motor to a pulley on the crank shaft of the engine, which in turn is connected to the induced draught fan.

The electric motor being exactly in

the centre of the two steam engines, this drive may be changed over from one fan to the other by merely slipping off the belt on the engine on one side and slipping on the engine on the other side.

The motor used for this purpose is a 20 h.p. Westinghouse induction motor, and the fan is 12 ft. in diameter.

Heating and Ventilating

The general heating, ventilating, and hot water equipment for the various buildings is of large dimensions, and of a comprehensive character.

There is a 30,000 C. F. M. fan and set of steam coils in the basement of the Parliament Buildings, for heating entrance vestibules, and main stair hall.

The suction of this fan is connected to re-circulation registers, in the main stair and central halls, also to the main steam pipe tunnel from the power house and to a fresh air shaft, at the roof level.

During the heating season this fan is operated to pull sufficient air through the tunnel to utilize the heat radiated from the 8 in. high pressure mains.

Approximately 35,000 sq. ft. of direct radiation is installed in the building, and about 12,000 sq. ft. of indirect radiation.

For ventilating the building six fans are used, two of which each have a capacity of 43,000 cubic feet of air per minute.

The necessary fresh air for these fans is taken in through a louvre opening at the ground level; this is heated and washed, and then discharged into large plenum tunnels in a sub-basement, from which galvanized iron flues are run to rooms above and there delivered about 8 ft. above the floors.

Fan No. 3 has a capacity of 16,000 cubic feet.

Fan No. 4 has a capacity of 30,000 cubic feet.

Fan No. 5 has capacity of 20,000 cubic feet.

Fan No. 6 has capacity of 7,000 cubic feet.

Manitoba's New Parliament.

The heating coils for the fans are the regular vento section, set on the inlet side of the fans and contain a total of 12,145 sq. ft.

Control Steam Supply

The steam supply to the coils is operated by temperature regulating valves and thermostats, which control the air entering the offices at any desired temperature between 60 and 80 degrees. The return connections to the coils are provided with float type traps.

Two vacuum cleaning machines are installed in the basement, each having capacity for operating four cleaning tools, while maintaining a vacuum of 9 inches. Vacuum cleaning pipes with outlets are distributed all over the building, the dust collected being washed into the drains. To permit the chief engineer to always observe the condition of this service, a pipe was connected to the instrument board so that the degree of vacuum maintained could readily be observed by the "chief" at any time.

The water supply is from the city mains. A 6 inch pipe runs into the power house and from there is boosted by two centrifugal pumps through the tunnel to 2, 10,000 gallon steel storage tanks in the dome of the building.

A 6-ton York refrigerating machine provides the necessary cooling system for the kitchens, and the drinking water.

The drinking water system consists of a cork insulated copper tank with 100 feet of ammonia cooling coil. This water is distributed by means of two centrifugal pumps. There is an open copper tank in the dome to which are connected 16 pedestal fountains in corridors and 14 fountains and drinking faucets in the various offices.

The system is downward to the fountains and by connecting the supply risers back to the cooling tank, a continuous supply is maintained. As it is necessary to maintain uniform circulation to the various branches of the water supply, lock shield valves are installed which automatically govern the system.

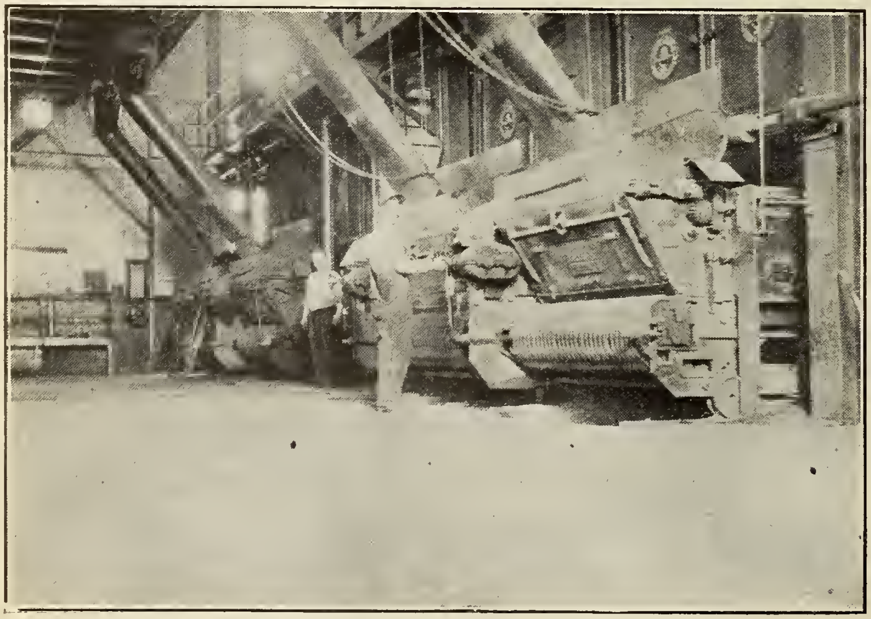
In a similar manner all the pumps in connection with this service are automatically controlled by float switches at the tank in the dome.

Hot Water System

The hot water is obtained from a hot water heating tank in the power house, this being heated by live steam from the economisers installed in conjunction with the steam boilers. Two centrifugal pumps located in the power house distribute the hot water. These pumps have a capacity of 380 gallons per minute. The insulation of all steam piping is of such an efficient character that it is seldom necessary to inject live steam to augment the temperature obtained from the economisers.

In all cases of central heating, after generating the steam efficiently, the important question arises of how to conserve the heat units in the steam and not permit them to be lost by poor insulation.

The method of insulation in this plant is of particular interest as it has a remarkable degree of efficiency. When walking along the main tunnels, one is not conscious of any uncomfortable degree of warmth although in close proxi-



Boilers and Chain Grate Stokers in Power House.

mity to several main steam pipes conveying high pressure steam.

Considering temperatures of the nature of 30 to 40 degrees below zero are of common occurrence during the winter months, the added importance of perfect insulations is readily appreciated.

The fresh air intakes between the outside walls and the first bank of heating coils, are insulated with two layers of 1 inch cork board. Air cell covering is on hot water piping, and wool felt is used on the cold water piping, whilst on the drinking water piping there is a cork insulation 2 inches thick.

Conduit in Tunnel

Where the buildings are connected by a conduit instead of a tunnel, the conduit consists of vitrified sewer pipe 8 inches in diameter. Special man-hole covers are inserted in the conduit at various intervals, and at all places where expansions joints are connected.

These conduits, the work of the Johns-Manville Co., are installed about 7 feet below the surface.

All steam pipe is covered with 85 per cent. magnesia covering, 2 inches thick on all high pressure mains, and 1 inch on low pressure, finished off with a water proofing varnish.

In large buildings it is a bewildering task to attempt to locate any defect which may arise on a particular piece of piping, due to the multiplicity of the number of pipes, sizes, services, etc. No such difficulty is apparent in this plant as each pipe is given a distinct color throughout the building, the color depending upon the particular service for which the piping in question is used. The color scheme of piping is as follows:

H.P. Steam, white with brass bands.

L. P. steam, white with black bands.

Domestic hot water, brown with black bands.

Heating hot water, brown with white bands.

Vacuum, yellow with white bands.

Return, green with white bands.

Air, grey with white bands.

This scheme was carried out by the Johns-Manville Co. and Hilton & Sons, of Winnipeg. It is to be highly commended and should suggest itself for adoption in any plant where a somewhat complex system of piping has to be installed for the distribution of the various water power and heating services.

The pump house is replete with modern equipment including:

2, Worthington feed pumps direct connected to 15 H.P. D. C. motors.

2, Centrifugal Pumps running at 1,800 Revs. 3 H.P. D.C. motors.

2, Centrifugal pumps running at 1,600 Revs. connected to 1-H.P. motor.

Chain Overhead Valves

All overhead valves are operated by chains, arranged at a convenient height.

To permit of a record being kept of the heating services, a complete system of condensation meters are installed on the various systems of heating.

Tunnel From Power House.

From these meters is collected each day the amount of water condensing in the heating system. This is measured in lbs. and entered in the daily "log" from which a complete statement is made up of the total cost of operating the central heating plant each month and presented to the Minister of Public Works.

The enormous figures attained by this condensation are worth while recording:

Condensation Water, from Heating System

For month in 1923:—

Parliament Buildings, 7,250,000 lbs. condensation.

University Buildings, 4,880,000 lbs. condensation.

Land Titles Buildings, 375,000 lbs. condensation.

Jail Buildings, 854,000 lbs. condensation.

The cost of generating 1,000 B.T.U's. in this plant is claimed to be 0.03655c per 1,000 B.T.U's.

T. M. Power is chief engineer of the plant and is also responsible for the efficient operation and maintenance of all the electrical and mechanical equipment of the Parliament Buildings.

Mr. Power is a Canadian born, and served his apprenticeship with the Mitchell Brass Works of Montreal. After gaining his experience in various large plants, he held several very important positions, being engineer in charge of construction for the Sturgeon Falls Paper Mill, Ont.; Chief Engineer, Lyle Construction Co., Montreal: Chief Engineer, Fort Garry Hotel, Winnipeg.

Mr. Power holds a 1st class engineer's certificate, and is a member of the Board of Examiners for engineer certificates in the province of Manitoba.

He is also Past Worthy Chief of the Universal Craftsmen Council of Engineers and a member of the Manitoba Electrical Association.

In addition to his professional interests Mr. Power is an active member of the Masonic Fraternity and the Order of Oddfellows.

PIPE LINES

UNCOVERED IN ANY OLD SPOT

Cracks or flaws in a smooth metallic surface can be rendered visible by thoroughly moistening the surface with kerosene, drying with a clean cloth and subsequently rubbing the surface with chalk. The location of flaws will be revealed by traces of the kerosene oozing from the cracks on the chalk surfacing.

* * *

Always remember that your brains can accomplish more in a boiler room than your boss's money.

* * *

In changing the speed of an engine, care should be taken to adjust the governor springs so that the sounds, when they are tapped with a hammer, will be as nearly alike as possible. If the sounds are different it is a case of unequal tension which will result in unequal strain and may cause racing.

* * *

There isn't any luck in the way the B.T.U. go through your boiler.

* * *

Do not stop a motor by turning the rheostat arm back to the "off" position and leave the line switch in. Open the line switch first and then note that the no-voltage release causes the rheostat arm to fly back to the "off" position.

* * *

Dirt on your hands doesn't clog up the machinery in your head.

* * *

A 220 volt shunt motor will run at 10 to 25 per cent. below normal speed when operated on a 110 volt circuit.

* * *

The safety valve capacity on a boiler should be such that the valve or valves will discharge all the steam that can be generated by the boiler without allowing the pressure to increase more than 6 per cent. above the maximum working pressure or more than 6 per cent. above the highest pressure to which any valve is set.

* * *

Is a chimney a device for organized waste? Or isn't it?

* * *

Every care should be taken to keep all high-pressure steam lines drained of water all the time. Water-hammer is dangerous and often responsible for fatal accidents and serious damage.

* * *

Our idea of nothing at all is the brain cavity of the man who never uses his rear boiler damper.

* * *

It is always good practice to use tees or crosses instead of elbows in bends in the feed-piping, so that the pipes may be easily washed and cleaned.

Universal Craftsmen at Anniversary Banquet

Spirit of Goodwill Dominates Canada Council No. 27 as Grand Worthy Chief Patton Urges Engineers to Humble Their Antagonists by Gaining Their Objective on Sheer Merit

CANADA Council No. 27, Universal Craftsmen's Council of Engineers, held the most successful banquet ever staged by the organization in the Oddfellows' Temple, College street, on April 23.

Well attended by out-of-town visitors and Toronto members alike, an enjoyable evening was had by everyone from the first hearty handshake to the last waltz.

A brief but satisfactory business meeting preceded the festivities at which the following visitors were present: Grand Worthy Chief J. M. Patton, Past Grand Worthy Chief Jos. H. Nicholls, Past Grand Worthy Chief H. C. Senn, Jas. Magill, St. J. Gample, S. R. Finley, H. Lawrence, and A. Johnson, all of Buffalo; S. E. Cosford, Wm. Barclay, G. A. Leckie, and H. Lindgar all of Hamilton, and Campbell Bradshaw, editor of Power House.

Among Toronto officers present were H. E. Terry, Past Grand Worthy Chief; L. J. Cudbird, Grand Trustee; Chas. L. Holmes, Worthy Chief; and W. J. Hudson, Secretary.

'Twas Scene of Gaiety

Following the business session, the Council chamber became the scene of much gaiety when the ladies arrived by the score to start the evening's entertainment with progressive euchre. J. R. Grimshaw, as official announcer, instructed the players in the rules of the game, with a zest that won the approval of everyone.

The winners in this feature of the program were: H. Potter, S. Nelson, P. Davies, Mrs. Stephen, Mrs. Albert Baker and Mrs. A. M. Auchterlonie. J. H. Morrison and Mrs. Bunting captured the booby prizes with ease. Handsome trophies were awarded the skilful disciples of Hoyle during the banquet. Curiously enough Mrs. Stephens, Mrs. Auchterlonie and Mrs. Bunting are sisters.

Mayor C. Alfred Maguire, of Toronto, an honorary member of Canada Council for several years, welcomed the visitors in a witty and entertaining speech. Mr. Maguire said he was proud to be a member of such an organization, and emphasized the part played by the Council in fostering the spirit of goodwill ever present in the hearts of the members. The mayor's address met with an enthusiastic ovation.

Following the official welcome the 200 guests descended to the banquet hall where a sumptuous repast had been prepared.

Mr. Patton, introduced as the youngest Grand Worthy Chief the order has ever had and one of the best, in a stirring talk on the success of the council emphasized the common ideals of all men and stressed the necessity of members working in harmony to attain the aims of the organization without ill-will to those of their fellows who possess ideas contrary to their own.

Anticipation seeks to protect gains made in the economy and efficiency of power house operation; to develop new ways to overcome waste, to determine what resistance may be met with—and where it is likely to come from, along with the development of steps necessary to meet it, that the engineer may proportion his efforts to the demands that may be made on them—all looking toward his ability to make events which will fit in with his objective.

Sink Bad Feeling

"Sink bad feeling and do everything possible for the good of the order," Mr. Patton urged. "Always do for your brothers in life what you would wish them to do for you. The secret of success lies in always treating the other fellow as you would wish him to treat you if you were in a like position."

After declaring that he was proud to be an honorary member of Canada and Hamilton Councils, Mr. Patton won the good will of the fair sex by declaring that there were more really beautiful women present than in any audience he had ever seen. At the command, however, of Mrs. Patton, he immediately had to admit that he was a married man although he reiterated his faith in Toronto's beauty.

That the Universal Craftsmen's Council should control the larger positions in all the cities of Canada and the United States was the firm belief of the speaker as he warned the members never to allow the order to lower itself to conflict with antagonists but always to gain an objective on a merit basis.

Will Come Again

In concluding Mr. Patton predicted that the order soon would have a Canadian chief worthy of its great traditions in the person of Mr. Cudbird and promised that he would again visit Toronto before his term of office expires in August.

Worthy Chief Holmes proposed the toast to The King, and the President of the United States, the audience responding with great heartiness. This was followed with a toast to the Grand Council, proposed by Brother Terry. Grand Trustee Cudbird then gave an able address on the question confronting the council as to whether to increase the membership, the order should transgress on other fields by permitting men engaged in other industries, such as plumbers, to become members of the Council.

In the opinion of Mr. Cudbird there is but one answer to this question and that an emphatic "No."

"Let the order embrace the cream of the engineers in every land and let it not look for larger numbers, but for quality, by keeping always to the present tradesman," the speaker said, commenting on the rapid expansion of both the Hamilton and Toronto Councils. He pointed out that in great part due to the popularity of Worthy Chief Holmes, Toronto had initiated twenty-five members since June.

Mr. Cudbird predicts the immediate dawn of an era of unparalleled success for No. 27.

The Grand Trustee was followed by Mrs. Nichols, of Buffalo, who gave an excellent talk on behalf of the Grand Council.

Can Move World

Mrs. Senn, of Buffalo, pointed out that since engineers alone can turn the wheels of industry, they should when aided by the weaker sex be able to move the world. Members were urged to develop kindliness and to help others to gain talents equal to their own, and above all things, to eliminate jealousy from their hearts and disregard bitter remarks. Mrs. Senn declared she was proud of her English parentage, her mother having been born in England. Amid much laughter she remarked that it were well that the teachers of Buffalo could not hear Mr. Patten's compliment to Toronto's fair sex, since that gentleman is chief engineer of Buffalo's Board of Education. Mrs. Senn here ended her remarks and was succeeded by Mrs. Geo. Aldridge, Chaplain of the Grand Council. Mrs. Aldridge stated that no one could be happier to be present at such a gathering, second only in the annals of No. 27 to the convention a few years ago. She heartily wished every member many happy returns on the Council's birthday. After this cordial talk which was well received, a handsome bouquet of flowers was presented to Mrs. Patton, wife of Grand Worthy Chief Patton.

In a brief reply Mrs. Patton said she was too tired to do other than thank everyone from the bottom of her heart for the kindness she had experienced. Brother Thos. McAree with a few well chosen words, then thanked the ladies for the hearty co-operation they had always given the Council in any project undertaken.

Was Star of Bill

Mrs. Darbyshire, wife of the chief engineer at the General Hospital, with a pleasing solo which was easily the outstanding vocal offering of the evening, received prolonged applause, and as an encore sang Tosti's Good-Bye. Mr. Morrison offered two splendid selections, accompanied by Mrs. Longmore at the piano.

Another exceptionally entertaining feature was a recitation by little Miss Johnson, entitled "On to the Bargain Store Rode the Six Hundred."

The entertainment was featured by the winsome Misses Jean "Babe" Russell and Agnes Russell in dancing and songs.

Howard G. Fletcher acted as accompanist for a number of jolly songs, such as: "Pack up your troubles in your old kit bag;" "All the nice girls love a sailor;" "Hail, hail the gang's all here," etc.

After Brothers G. A. Leckie and S. E. Cosford, of Hamilton, had congratulated No. 27 on its birthday, W. R. Sexton took the gathering by storm with the Power House Orchestra, composed of J. L. Percy, J. A. MacTaggart and K. W. MacTaggart. When the tables had been cleared away and the room made for enthusiasts who had remained, everyone indulged in fox trots and waltzes, which were featured with the swan-like dips and glides of Mr. Sexton.

By this time, the wee sma' hours were creeping by, and with the last strains of "Three O'Clock in the Morning" throbbing on the air, Canada Council, began its entry upon its year of majority, with the good wishes of everyone prophesying one of the most successful years in its history.

Regret was expressed at the absence of Wm. J. Ranton of Rochester, N. Y., Past Grand Worthy Chief, who from far off Kansas City, Mo., sent members his best wishes for a happy and enjoyable anniversary.

To dry out a generator run it with the armature short-circuited beyond the ammeter and circuit breaker and adjust the field so as to maintain a temperature in the winding of 58 deg. Fahr. This should require approximately full-load current.

Good oil without adulteration, if used intelligently, is cheaper and more satisfactory than cheap oil, loaded to give bulk and to make it apparently cost less per gallon.

Leaky boiler settings may be made lastingly tight by soaking cheap waste or asbestos from old discarded pipe covering in thin fireclay and hammering the mixture into the cracks. Paint the brickwork with thin cement.

Can Every Fat Man Defy Heat?

Engineers Find Stout Firemen Lose Weight But Retain Vigor at High Temperatures

FAT men endure high temperature and humidity better than thin men. This fact has been proved in scientific research conducted by the American Society of Heating and Ventilating Engineers, in co-operation with the Carnegie Institute of Technology.

In experiments to determine the relative effect of various temperatures and humidities on the human body, the scientists also found that sweat is the chief factor causing sore eyes, when a person becomes heated.

Another common belief was blasted during the experiments when they found that the drinking of ice water failed to develop cramps in men after they had been subjected to an hour's exposure to high temperature.

The object of the research work is to establish, by scientific study, the exact degree of temperature, and of humidity, or "comfort lines" a person should be subjected to in a room.

Can Endure Variations

One of the important results of the experiments was the discovery of the great variations of external temperature which the human being can endure, and at the same time, retain his physiological efficiency. Another fact discovered was that increasing pulse-rate is more the cause of discomfort than is body temperature, when in a heated room.

In a report of the experiments, just issued, are these assertions: While irrelevant to the present study, an attempt was made to determine the cause of the inflammation of the eyes, and also to find out whether or not drinking of ice water produces cramps, as so frequently complained of by workers in the industry.

"On a day when the eyes were normal, small quantity of sweat which had been collected during an experiment, was dropped in the eye. The conjunctiva almost immediately became inflamed and the eye felt sore. The sweat collected from the face seemed less irritable to the eye than that collected either from the chest or arms. Sweatbands were then applied to the forehead during the experiments, these preventing the sweat from falling into the eyes, and also prevented the inflammation. This proves sufficiently that sweat is the chief factor in producing the conjunctivitis which accompanies exposure to heat.

No Cramps Develop

"It has frequently been stated that workers, such as firemen, exposed to high temperatures developed severe cramps after drinking ice water. A few of the subjects of these experiments volunteered to drink ice water after about an hour's exposure to high temperature, and two of them, in one experiment, drank a quart of ice water in less than 15 minutes without ill effects. Cramps did not develop in any of the subjects at any time."

On entering and leaving the specially heated chamber the report shows, loss of weight varied with the individual, the heavier and stouter man losing more than the light and thin one. Notwithstanding this, the lighter man as a rule could not endure the temperature conditions as long, and complained more of the exhaustion which followed.

Book Reviews

MACHINERY FOUDATIONS AND ERECTION

By Terrell Croft. Published by McGraw-Hill Book Co., New York City. Cloth; 5½ x 8 in.; 668 pages; 772 illustration. Price, $5.

This volume is one of a series which the author has prepared upon steam power-plant practice. Nothing new is presented beyond the development of formulas for the calculation of foundation bearing surface and volume.

Unfortunately, the data given as to safe bearing pressures are so much beyond those encountered in machinery-foundation building that the formulas are of doubtful practical value. The pressure values given evidently are those where some settlement of the masonry is permissible. Needless to say this is quite undesirable in engine foundations.

As the author points out, the framing of most machines is such that the area within the foundation bolts exceeds the required area as derived from the formula. Most of the pages are devoted to methods of constructing foundations, aligning and erecting machinery and other data of considerable value to the engineers.

While the volume is in many respects a compilation of material that has appeared in various technical publications, this matter is so logical in arrangement and so complete in treatment that a considerable popularity is to be expected for the work. It would seem that it should be of particular benefit to machine designers and erectors, consulting engineers and architects.

A simple method of determining the polarity of the wires of a direct current circuit is to place the two leads about ¼ in. apart on a piece of moistened blue-print paper. The paper around the negative will turn white. It is well to place a lamp in series with one of the leads to avoid a possible short circuit.

Corrosion Problems in Modern Plant Equipment

Basic Principles of Feed-Water Troubles—Causes of Corrosion From a Chemical Standpoint and the Practical Application of Effective Prevention in Boilers and Economizers

IT IS proposed to deal in this article with the underlying causes of one of the problems which continually confront those who deal with the production of steam power—corrosion in boilers. While the process of corrosion is essentially chemical, the reactions taking place are of such a nature, and the basic principles upon which they operate so clear, that it is possible for any stationary engineer to become thoroughly familiar with them without the necessity for wading through realms of seemingly vague technicalities.

General Troubles

Since we are here concerned with the question of corrosion only it is possible at the beginning to eliminate the three other difficulties in boiler operation due directly to the water—priming, foaming and scaling. The first two of these are surface tension, they are ebullition or boiling phenomena whose symptoms are the faulty distribution of boiler water. Scaling and corrosion are sharply differentiated since, with a single exception, one rarely accompanies the other.

Scale, consisting chiefly of silicates, amalgamates with the boiler wall and destroys its smoothness. In addition, when it is removed it takes with it a film of the metal, gradually weakening the walls. As scales, these silicates are excellent heat insulators and are not entirely impervious to penetration by boiler water. The corrosion caused by them is primarily mechanical and is due to localized overheating at the boundary surface. Aside from the silicate, boiler scale is a most excellent preservative, being far superior to any paint which it is possible to apply.

Theories of Corrosion

Corrosion proper, is a chemical reaction between the boiler wall (metal) with one or several of the constituents of the boiler water. The ultimate result of this continuous process is the solution of the metal. There are three theories generally put forth in explanation of these reactions: Whitney's Electrolytic Theory; Calvert's Carbonic Acid Theory and the more recent Colloidal Theory of Friend. Each of these differs from the others in the details of the argument but all are founded upon the same generalities. It is to these latter that we shall devote our attention.

Mind is the basis of all business organization. Brawn alone in the midst of present day production machinery is more or less worthless. The big economic force is not merely man power or the instruments of which man power makes use, but mind power. It designs and builds power plants, factories and skyscrapers. It opens up mines, cuts down forests, and turns dry lands into garden spots.

Basic Reactions

These major premises, however, include practically all the observations which it is possible to make and are therefore the sort of information of value to the engineer in the field. The chemical equations of the electrolytic theory are the most direct and we shall use them as an example of the general process. They are listed here for reference and on the basis of the greatest convenience.

(1) $\text{Fe}+2\text{H}(\text{OH}—\text{Fe}(\text{OH})_2+\text{H}_2$
(2) $2\text{H}_2+\text{O}_2—2\text{H}_2\text{O}$
(3) $4\ \text{Fe}(\text{OH})_2+\text{O}_2+2\text{H}(\text{OH})—$
$4\ \text{Fe}(\text{OH})_3$

Very little chemical knowledge is needed to understand the mechanism of the reactions for which these equations are an abbreviation. We are all familiar with the fact that water is ionized into two particles called ions, which carry electric charges of an opposing nature and which are designated as hydrogen ions (H) and hydroxide ions (OH). Iron by virtue of its position in the arrangement of the elements according to their electrolytic activity, is able to displace the hydrogen ion from solution, depositing hydrogen gas upon the iron surface, and itself going into solution as ferrous iron. The extent of this interchange is the first consideration in dealing with corrosion.

Ionization

For water, the product of the concentration of the hydrogen and hydroxide ion is a constant quantity. It is impossible to increase one without simultaneously decreasing the other. Increasing the hydrogen ion concentration increases the acidity and likewise the corrosion. Upon these facts are based several observations of a very practical nature.

Alkalinity, or causticity of a boiler water is usually associated with softening either by the zealite or lime-soda process. In practice, alkalinity and causticity are rather sharply defined---alkalinity being due to carbonate additions of sodium and causticity to hydroxide additions---while from a chemical viewpoint, both are alkaline. Very frequently, the selection of carbonate instead of sodium hydroxide is a matter of cost rather than of the best practice while on the other hand, many recommendations made for corrosion prevention may not accord with minimum operating costs in softening processes.

The addition of caustic soda by the direct addition of hydroxyl ions, or the addition of sodium carbonate with its resulting hydrolyzed product, increases the concentration of hydroxide and simultaneously decreases the hydrogen ion concentration and corrosion. This, however, is a broad statement which requires some reservations.

General Exceptions

In spite of our chemical logic set forth above, it is true that relatively pure waters, made alkaline by the addition of sodium carbonate are much more corrosive than the water in its original state. Generally speaking, therefore, the addition of sodium hydroxide is to be preferred to the addition of sodium carbonate. The only cases where sodium carbonate ever approximates the protective value of the hydroxide are those of waters containing appreciable quantities of chlorides and magnesium salts, such as sea water.

The addition of caustic soda or sodium carbonate to boilers operating on distilled water produces practically no benefits. With natural waters, fed into the boiler in the raw state, without distilling, the addition of sodium in either of the two forms mentioned is much more beneficial, but very much depends on the nature of the other totally soluble salts, which, in ionized form, affect the concentration of the hydrogen ion.

Negative Ions

The order of corrosion due to soluble and ionized salts in boiler water from the standpoint of the negatively charged ions which they produce, is as follows: Nitrates, chlorides, sulphates, chromates and arsenates. It is impossible to suppress corrosion in a water carrying nitrates by the use of soda. These nitrates, however, ordinarily originate from pollution and nitrate waters are comparatively rare. With chloride waters, sodium carbonate is perhaps more useful than sodium hydroxide, but the order of the merit is open to dispute and neither of them will prevent corrosion, but only minimize it. With predominantly sulphate waters containing magnesium in particular, high causticity is almost a complete corrosion preventive. Chromates and arsenates are usually compounds which are added to boiler water to help out the addition of other corrosion preventing reagents and do not occur in natural water. They are most useful in the case of boilers operating upon comparatively pure water.

Positive Ions

It is desirable at this junction, to make some mention of the other ion in the combination for dissolved salts, viz —the ion carrying the positive charge.

The bivalent ions in this case produce more corrosion resistance than the monovalent, and the trivalent more than the bivalent. This, however, is significant only where other reagents are to be added to comparatively pure water to make up for the deficiencies of caustic.

It is possible to summarize the conclusions in the foregoing paragraphs by saying that causticity or the addition of sodium hydroxide serves best with impure natural waters, containing very considerable quantities of dissolved solids.

There is still to be considered the bugaboo of operating engineers—caustic embrittlement of the boiler metal with high hydroxide concentration. This has been a real and serious difficulty in certain localities, either from industrial pollution as in by-product and alkali works or in certain localities where the subterranean water was heavily charged with carbonate of soda. It is not a corrosion phenomena in the sense that we have previously described corrosion in this paper, but rather an osmotic penetration of gases into the metal, and a subsequent embrittlement. Fear of caustic embrittlement has deterred and will deter many engineers from the use of sodium as a corrosion preventive. It is still so mysterious and its occurrence has been so comparatively rare that no definite explanation for its prevention can be offered.

Raw Feed Water

Where causticity is used for corrosion prevention in boilers using raw water, it is necessary to work out a scale of blow-down concentration by experiment. As boiler waters concentrate over periods of operation, the conditions of soda alkalinity change also, and for complete control it is necessary to supervise boiler concentrations closely. This makes the use of causticity very tedious. Foaming or priming occurs only with a combination of high alkalinity and suspended matter in the boiler water.

Dissolved Gases

One other, but very vital criticism of causticity in boiler water is to be noted, and it may very conveniently furnish an introduction to the succeeding section. We shall next speak of the influence of dissolved gases and in particular, dissolved oxygen, and before leaving the subject of causticity, it is to be noted that the oxidation of the primary corrosion, ferrous hydroxide, which is a feature of dissolved gas corrosion to be stressed in later paragraphs is accelerated in alkaline solution. This is a very significant objection in the case of boilers fed with distilled water.

A second factor influencing corrosion, viz.—dissolved gases and in particular dissolved oxygen, has been intimated in the previous paragraph. Equation 1 of our previous discussion is still useful in explaining this form of attack on the metal, but it is necessary to consider also equilibrium conditions which are dependent upon equations 2 and 3. Equation 1, from the chemist's standpoint, is a reversible reaction, which does not go on indefinitely in one direction, but on the contrary has natural limits, which occur when the electrical forces, producing the solution of the metal in the water, are exactly balanced by the electrical forces in the solution. These electrical forces counterbalance each other with a very minimum amount of solution, determined by the concentration of the dissolved product, not enough in the lifetime of a boiler to produce any trouble.

Reversible Reactions

The solution of iron in the boiler water occurs, by the inter-change of hydrogen and iron, the iron going into solution and depositing the hydrogen on the metal surface. This deposited hydrogen gas film would speedily polarize the metal surfaces and add its influence to checking the reaction, if it were not promptly destroyed by the dissolved oxygen in the water through the same chemical reaction, which produces the water (equation 2). This is the first step in the destruction of the equilibrium condition of equation 1, which nature would otherwise impose.

The important thing in any work is happiness and contentment. An engineer may be capable of filling the very highest places in engineering circles yet may prefer the dirt and grime of problems solved to the honor and income of a higher place. Of such men there are many in the world. We look at them and pass by, just a wee bit sorry, but as we look back, we see a puzzled look on their faces because we do not see their point of view any more than they have seen ours.

The natural equilibrium of equation 1 is displaced still further by dissolved gases. The corrosion product ferrous hydroxide, $Fe(OH)_2$, is soluble in water. However, in the presence of dissolved oxygen in the water, ferrous hydroxide is oxidized to ferric hydroxide, which is insoluble. Dissolved oxygen in the water, therefore, removes the solution product, whose concentration, in a large measure, by virtue of electrical forces in the solution, was responsible for equilibrium. This is illustrated in equation 3. The natural checks upon the attainment of equilibrium are, therefore, removed and the limit of corrosion, instead of being the presence of a minimum amount of dissolved ferrous hydroxide, is now the complete elimination of the oxygen from solution by corrosion processes. This is a most serious feature, since the dissolved gases are in sufficient quantity to produce a very decisive attack on the metal.

These statements as before, furnish a groundwork for understanding the influence of dissolved gases on corrosion in a theoretical way. To this discussion also may be added certain pertinent facts which experience develops.

The fact that the oxidation phenomena, as abbreviated in equation 3, is a reversible process, is most significant. The reversibility is, however, what one might call polarized, in the sense that it proceeds from left to right much easier than it does from right to left. However, below .6 c.c. per liter of dissolved oxygen (cubic centimeters per liter being the usual means of expressing dissolved oxygen content in water and correspondig to parts per thousand by volume), the equation proceeds in some slight degree in this reversed direction, the velocity increasing as the oxygen content reduces, and if pipes heavily corroded from previous oxygen contamination are fed with air-free water, the product of the previous corrosion is reduced in some measure by the de-oxygenated solution and the products become soluble and detached.

Layer Corrosion

Usually observation of corroded pipe sections will indicate two or three layers of oxide, the ferrous closest to the metal surface; the ferrous-ferric next, and finally the ferric. The ferrous-ferric, Fe_3O_4, is to be regarded merely as a mechanical-chemical mixture of the ferrous and the ferric. Color of the oxide layers varies with the water of hydration; usually they are black, brown and red in the order named. The ferric oxide constituent serves as the binder for conglomerating all of the oxides and any scale present and the change in the reversibility by reducing the ferric hydroxide, destroys this binding action and clears out corrosion products at a slow rate. It is to be expected, therefore and experience coincides with this, that corroded surfaces will be cleared of their corrosion products. This is a big operating advantage in connection with deaerated water in hot water sanitary systems, where pipe stoppage from corrosion products is a formidable factor.

We have discussed, perhaps at the expense of apparent sequence, the facts that ferric hydroxide was insoluble and also that it has considerable cementing action. These two facts have a further significance. Ferric hydroxide in the solid form has a solution electrolytic potential different from iron, and as a result, acts when imbedded in an irregularity of the iron surface, as one electrode of a most excellent electrolytic cell, which continues the attack on the metal and produces a characteristic pit hole. Several things may produce chemical oxidation besides oxygen. One of them is electric currents as in the case of the pit hole formation.

Pitting

The corrosion due to dissolved oxygen which is most serious is pitting, and it is necessary to differentiate sharply between ferric and ferrous corrosion. The ferric corrosion produces the pit hole through the formation of electrolytic couples, as previously outlined. The ferrous corrosion, where it occurs, is a very uniform wasting of a metal at a slow rate. Sharp oxygen limits do not exist as transition points. It is possible that this is due partly to our facilities for observation, but it is more probable that it is gradually changing phenomenon. It is safe to say, however, that present experience with a variety of waters indicates that .6 c.c. per liter is sufficient to produce some reverse reaction in equation 3, and some freeing of pipes from corrosion products. The amount of corrosion is proportional always to the concentration of dissolved oxygen. This limit .6 c.c. per liter is therefore the upper limit at which some control of the form of the corrosion product is first exercised. Definite pitting, however, has been experienced with boiler waters of continuous oxygen content as low as .15 c.c. per liter. Corrosion has not been experienced with waters which have been de-aerated and have values substantially zero to a trace, a trace being defined as less than .2 c.c. per liter. The middle ground, as far as the writer is aware, between these values—.025 and .15 is still unexplored and will be explored only when practical operating values are available.

A remark made previously, that the difference in electric potential between iron and precipitated iron hydroxide was responsible for the pit hole formation, suggests the advisability of using high water velocities to prevent ferric hydroxide lodgment, in other words to wash out the hydroxide rather than have it adhere. It is possible to secure some merit by using high water velocities, but the velocity required is in the neighborhood of the condensor range and considerably above turbulence, the minimum useful value being about 4 ft. per second. Such velocities are impossible in natural circulation of boilers and cannot be maintained except under conditions of high load and high pumping loss in economiser practice.

Oxygen

It is desirable at this point to summarize oxygen corrosion prevention very much as we have previously summarized hydroxide corrosion prevention. Dissolved gas removal with pure waters is a corrosion preventive. With acid waters having a high hydrogen ion concentration, it is an inhibitive. It cannot prevent the attacks due to the acid pollution, but it can very definitely prevent any regenerative action. Neither can the removal of dissolved gases prevent the pitting of defective material, which, in the process of manufacture has segregations of manganese and mill scale to produce electrolytic couples. Commercial boiler materials have proven sufficiently pure to avoid this objection. Aside from these, it is more useful than causticity in that it aims directly at the seat of the trouble. Addition of soda protects only the boiler; the economizer is included only when the caustic feed is continuous, as with 100 per cent. make-up. Corrosion may be suppressed in the boiler by hydroxide ion concentration and reappear again where the steam is condensed as a typical case of dissolved gas corrosion.

Having dealt fairly generally with the underlying principles of corrosion in boilers we will now turn our attention to economizers or feed water heaters in particular and observe how the facts which we have outlined find application in one of the most important pieces of equipment in the modern plant.

Much has been heard in recent years regarding ways and means for the utilization of waste heat, presumably owing to increased fuel costs and a general call for economy. In work of this nature, particularly in connection with internal combustion engines, considerable duplication of effort might be avoided by reference to several means which have contributed to the efficiency of such plant for many years. In boiler practice it is safe to assume that every basic principle of waste heat utilization likely to be used for many years to come has already been applied. Forced draught, feed water heaters, special furnace tubes, and internal combustion heaters, super-heaters, water tubes and mechanical stokers have all contributed their quota to boiler efficiencies, and are the outcome of years of practical experience in the production and utilization of as much steam as possible for a minimum consumption of fuel.

It is proposed to deal in this section more particularly with economisers or feed-water heaters, with special reference to the corrosive influences to which they are subjected.

General Principles

The aim in boiler design to communicate to the water as much as possible of the heat generated, it follows that the temperature of the flue gases should be reduced to a minimum before going to waste; and this may be effected, within certain limits, by providing a maximum heating surface for a minimum grate area.

One method of increasing the effective heating surface is by introducing an economiser, a system of tubes through which the feed water passes and receives heat from the flue gases in which it is stationed. Where economisers have been installed in steel mill plants a regular saving of 10 per cent. in fuel costs has been made. Forced draught is necessary in connection with the use of economisers.

Other Types

There are other types, of feed-water heaters in which the water passes through brass tubes which are heated by exhaust steam from an engine; but we are mainly concerned with economisers as understood by a series of cast-iron or wrought steel tubes, conveying the feed water and set in the flues. whence they utilize some of the heat of the combustion products, which otherwise would escape by the smoke-stack. A typical economiser of this nature consists of several vertical cast-iron pipes about 4 in. diameter and 9 ft. long, communicating at the top and bottom by longitudinal headers, known as boxes. These boxes are connected by top and bottom branch pipes, situated on opposite sides of the economiser and outside the brickwork by which it is surrounded. The feed water is pumped into the economiser through the bottom branch pipe near the point where the flue gases enter. The economiser should be situated in a by-pass in the main flue, in order that it may be cut out of action by a damper, to facilitate inspection without shutting down steam. An automatic scraper travelling up and down continuously to keep the surface free from soot should be provided on each tube.

Corrosion Conditions

Economisers are subjected to the most corrosive conditions prevailing anywhere in a boiler plant, the tubes being attacked on the inside by the feed water and on the outside by the gases and vapours of combustion, as well as by soot, which, when moist, may be highly corrosive. It is only comparatively recently that economisers of the type set in the flues have been made of any other material than cast-iron but, with the adoption of higher steam pressures than formerly, wrought steel economisers are finding favour, by reason of the great resistance which this material offers to bursting. The wrought steel tubes are lighter and occupy less space than those of cast iron. but these advantages are offset by the fact that the steel is considerably more corrodible; and it is only on account of its superior strength that it has been called into service in economiser work. Wrought steel tubes, having a safety factor of the same order as the actual boiler, which can be attained also with cast-iron but only with considerable complication, have been rendered useless by internal corrosion after less than twelve months service.

Prevention Means

Although economiser tubes whether of cast iron or wrought steel are very susceptible to corrosion effective measures can be taken to mitigate this trouble, and, indeed, in the case of wrought steel must be taken if the tubes are to render any useful service at all. Internal corrosion as already stated has been known to necessitate replacement of wrought steel economiser tubes within one year. Such rapid depreciation is mainly due to dissolved oxygen in the feed water. and may be lessened by the use of one or other of the available appliances which provide means for heating the water in an open heater and withdrawing the dissolved gases under vacuum in another vessel. With cast iron economisers the final oxygen content, after de-aeration of the feed water, should not exceed .03 per cent., or three parts of 10,000 and where wrought steel tubes are used, two parts in 10 000 or .02 per cent. is the working limit. A de-aerating plant suitable for use with cast-iron is not necessarily suitable therefore, if wrought steel condenser tubes are used.

A.S.M.E. Makes Plans for Spring Meeting

DEFINITE plans are being made by the executive committee of the American Society of Mechanical Engineers for the spring meeting which is to be held at the Mount Royal Hotel, May 28 to 31. At their invitation, the Canadian Engineering Institute is co-operating in the arrangements for the convention and the Montreal branch is taking care of local requirements. It is expected that about 600 delegates will be in attendance from all over the continent.

The program of the convention itself will be largely of a technical nature. In addition to the general sessions on the opening day, there will be technical sessions on following days devoted to the following subjects:—Power, textiles, machine shop practice, management applied to the pulp and paper industry, port development, fuels, railroads and general mechanical engineering.

Following will be found the daily program, by sessions:

Monday, May 28

Morning—(Morning sessions at 9.30) Council meeting.

Afternoon—Business meeting. Address by Calvin W. Rice, secretary, A. S. M. E., on his South American trip. Public hearing on power test codes.

Evening—Joint dinner at St. James Club, Council of the Engineering Institute of Canada, and Council of A. S. M. E.

Tuesday, May 29

Morning—Power development in the Province of Quebec, by Julian C. Smith; Development of Hydro-electric Power Plants in Ontario, by Frederick A. Gaby; Management Engineering as applied to the Pulp and Paper Industry, by R. B. Wolf; Practical Laboratory and Drawing Room Course in Industrial Engineering, by M. A. Lee; Street Car Construction at the Angus Shops of the C. P. R., by H. R. Naylor; Notes on Some Recent Developments in Railway Motor Cars, by C. E. Brooks.

Afternoon—Excursions.

Evening—Smoking Concert, by the Montreal Branch of the Engineering Institute of Canada, in the Mount Royal Hotel.

Wednesday, May 30

Morning—Bleachery Engineering and Operation, by F. P. Bascom and J. C. McDowell; Port Development, by R. S. MacElwee; Harbor of Montreal, by Frederick W. Cowie; Modern Hydraulic Turbines of Large Capacity, by H. G. Acres; Sectionalization and Remote Control of High-Pressure Steam Lines, by Peter Payne Dean.

Afternoon—Excursions.

Evening—Dinner Dance.

Thursday, May 31

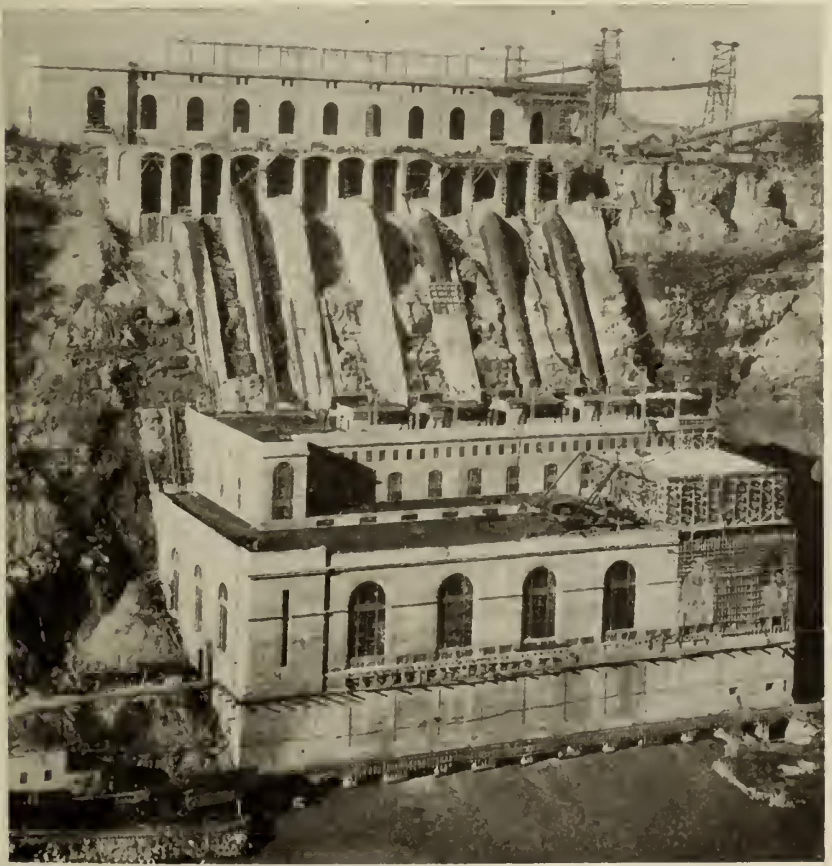
Morning—Recent Developments in Balancing Machines, by Carl R. Soderberg; Machine Tool and Paper Industry, by G. E. Williamson; Chimney Design, by A. Cotton; Lignite Char, by O. P. Hood; Endurance Test Data and Their Interpretation, by K. Heindlhofer and H. Sjovall; Bending Stresses in Curved Tubes of Rectangular Cross-Section, by S. Timoshenko; Control of Flying, by the Aeronautic Division.

Afternoon—Excursions.

The executive of the A. S. M. E. is also planning for those members in New York, New England and Eastern States, an automobile trip to Montreal. This trip will be taken by way of New York-Albany-Plattsburg-Montreal. A plan has also been arranged for those from the Western States to make a visit to the Queenston-Chippawa Power Plant on the way by train. Those members will meet at Niagara Falls, Ont., 10 a. m., Sunday, May 27, and visit the power plant, then going forward to Toronto by train, leaving for Montreal Sunday night.

While in Montreal, several interesting industrial visits will be made. The excursions will be planned as follows:—Tuesday—C. P. R. Angus Shops and Cedar Rapids Manufacturing and Power Co. Wednesday—Montreal Harbor and the plants of the Canadian Vickers Co., and the Frontenac Brewery. Thursday—Dominion Engineering Works and the McGill University. Other trips will include St. Anne de Beaupre, St. Helen's Island, Mount Royal Park, Art Gallery, Antique Buildings in Montreal, and the Lachine Rapids.

A ladies committee has also been organized, with Mrs. Fred B. Brown as chairman, to arrange a program of entertainment for the ladies of the party.



General exterior view of Queenston-Chippawa Hydro Power Station.

CORROSION PROBLEMS

(Continued from page 28)

The water should, of course, be as pure as possible and free from mineral acid.

External Corrosion

External corrosion of economiser tubes is caused mainly by condensation of moisture from the flue gases, and may be prevented to a large extent by maintaining the temperature of the feed water in the tubes at from 120 deg. to 175 deg. Fahr. The exact figure will vary probably in particular circumstances, but for most work 140 deg. F., will provide sufficient heat in reserve to cope with intermittent working, during which the liability of moisture to condense, if the tubes are allowed to cool, has to be reckoned with. The difficulties of countering external corrosion in intermittent service are increased also by soot, which, collecting on the outside of the tubes, is liable to become moist when the economisers are shut down or during starting up. Moist soot may be highly corrosive, especially if derived from fuel having a high sulphur content. The feed water should always be kept at a slightly higher temperature in the economisers when coal of a sulphurous nature is being burned.

Why Flue Gas Analysis Talks Furnace Efficiency

Three Simple Requirements of Combustion Apply to All Fuels, Namely, High Temperature, Proper Air Supply, and a Complete Mixture of the Air With the Fuel Gases

ANALYSIS of waste gases has come to be an accepted method of determining the completeness of combustion, the efficiency with which fuel is consumed, whether it be coal, oil, gas or refuse.

There are three parts of CO$_2$ in 10 000 parts of air—an insignificant fraction—but if the air were to be robbed of it, all vegetation would cease upon the earth, all plants would die, for plants live very largely upon carbon, and they get it all from the air. With the end of plant life would come the end of all animal life.

High fuel bills, freight rates and the like have all combined forces in pointing out the importance, the economic necessity of analyzing flue gases as a guide to the proper regulation of draft and the feeding of fuel, and as an index to the condition of baffles and settings and the efficiency of firing methods.

Steam Production Economy

To make steam with economy, two things are necessary:

Convert sleeping energy in fuel into live heat energy.

Transfer as much as possible of this heat energy to water in boiler.

The first of these has to do with the furnace; the second has to do with the boiler. The degree to which they are accomplished is expressed in the combined efficiency. **Gas analysis has to do with furnace efficiency and furnace efficiency is the controlling factor in combined efficiency—the key to high boiler room economy.**

The quality of the fire may vary to such an extent that it will cause all of the heat to be wasted, or make useful to the boiler as much as 85 per cent. of it. There is necessarily a loss of about 15 per cent. due to the fact that the gases must leave at a higher temperature than they enter.

What is Combustion?

Combustion is a chemical process. It is a process of oxidation or the chemical union of an element with oxygen. Combustion may be slow and accompanied by little heat, as when iron rusts, it may be more rapid, as when it occurs in the lungs of animals, it may be still more violent. as when coal is burned in a furnace; it may be instantaneous, as when powder is exploded in a gun barrel.

The principal combustible elements in fuel are carbon, hydrogen and sulphur. Three simple requirements of combustion which apply to all fuels are: (1) high temperature, (2), proper air supply, (3) complete mixture of this air with the fuel gases.

The supporter of combustion, oxgyen, is a chemical element. In its free state it occurs as a gas. The oxygen for the combustion with which power plant men are concerned is provided by the air, which is a mechanical mixture, not a chemical compound. It is important to distinguish between "Mechanical" and "Chemical" union. Oxygen is found in water in chemical union with hydrogen. It requires more or less energy to separate elements chemically combined. Little or no energy is required to separate elements mechanically combined.

> **It's lucky a man possesses the monkey trait of imitation. Engineers must read how other men have succeeded that they may imitate, not their exact methods, but their persistence, their efficiency and their energy. They must read about what they did and how they did it—to win out themselves.**

Hence it follows that the oxygen of the air is substantially free to combine with the carbon contained in coal, while the oxygen contained in water or carbonic acid gas is not free to enter into such combination. Apply air to the furnace fires and combustion flourishes—apply water or carbonic acid gas and combustion ceases.

Composition of Air

When the oxygen in the air passes through a hot bed of fuel or into the heated combustion chamber of the furnace, it unites with the carbon of the fuel to form a gas known as carbon dioxide, which is represented by the symbol CO$_2$.

Air can be said to consist of 79.3 per cent. nitrogen and 20.7 per cent. oxygen by volume, as the minute quantity of other gases that may be present, such as sulphur dioxide, ozone, carbon dioxide, moisture, etc., are negligible from the point of view of flue gas analysis.

Nitrogen performs no useful office in combustion and passes through the furnace without change. It dilutes the air, absorbs heat, reduces the temperature of the products of combustion, and is the chief source of heat losses in furnaces.

The combustibles with which we are concerned in the order of their importance are carbon, hydrogen and sulphur. (In steam engineering the term "combustibles" is applied to that portion of the fuels which will burn. Sometimes oxygen and nitrogen and other gases together with what is called "water of composition" are included with the combustibles but this is not correct.) The product of the combustion of carbon is carbon dioxide; of hydrogen, water; and of sulphur, sulphur-dioxide. The reactions in all three cases give off heat.

Combustion and Heat

Combustion is perfect when the combustible unites with the greatest possible amount of oxygen, as when one atom of carbon unites with two atoms of oxygen to form carbon dioxide, CO$_2$. $C+2O=CO_2$. Combustion is imperfect when complete oxidation of the combustible does not occur. Sometimes the volatile matter is distilled and passes off without burning at all. Again, the combustible may not unite with the maximum amount of oxygen, as when one atom of carbon unites with one atom of oxygen to form carbon monoxide, CO, which may be further burned to carbon dioxide. $C+O=CO$. $CO+O=CO_2$. When carbon is burned completely there is liberated 14,600 B. t. u. for every pound of carbon burned but when it burns to carbon monoxide only 4,550 heat units are liberated. If carbon monoxide can be burned to carbon dioxide the additional 10,150 B. t. u. are given up.

A mere statement of these facts might prove to be misleading by offering an exaggerated idea of the importance of CO. There is little danger for CO in boiler furnace gases when the CO$_2$ content is less than 15 per cent. With a little experience you can learn to recognize the furnace conditions that are likely to produce CO, and when these are observed you should test for CO with a hand analyzer. When it is considered that an average of a great many analyses showed less than 25/100 of 1 per cent. CO and that only under conditions resulting from bad firing could as much as 1 per cent. CO be found the problem of trying to automatically record this percentage becomes apparent. The first problem is to find the conditions and methods that will produce above 10 per cent. CO$_2$. Only in comparatively rare cases is a steam user sufficiently interested in his boiler plant to adopt good methods of firing, see that the brickwork does not leak, and get the CO$_2$ percentage up toward fifteen.

Kindling Temperature

Before combustion can take place we must first raise the combustible to the kindling temperature which varies with different fuels. Curiously enough, the gases have higher ignition temperatures than the solid fuels. The ignition temperatures for gases range from about 900 deg. to 1,400 deg. F., and for the coals from about 600 deg. to 1 000 deg. F.

For every three pounds of carbon that we burn in the furnace we send 11 pounds of CO_2 up the chimney, mixed with several times its weight of nitrogen.

If the fuel were pure carbon and if all of the oxygen combined with the carbon as it passed through the fuel bed the resultant gas would be 20.7 per cent. CO_2 and 79.3 per cent. nitrogen. In practice, however, it is found that excess air has to be introduced to insure complete combustion of ordinary coals and other fuels. For coal this excess should be somewhere between 20 per cent. and 60 per cent.—usually about 40 per cent. This lowers the percentage of CO_2 in practice to from 13 per cent. to 15 per cent., depending upon the nature of the fuel. Pulverized fuel, and oil can be burned with a smaller proportion of excess air since an intimate mixture can be effected.

Fuel Variation

The terms "coal," "fuel," "oil," etc., are general terms only. Coal may range from almost straight carbon with only a trace of volatile matter to a fuel that is more than 50 per cent. volatile. It may contain all the way from a trace of sulphur to as much as 10 per cent. or more. Crude petroleums vary in their compositions in about the same way as bituminous coals. The heat values range from 17,000 to 20,000 B. t. u. Sulphur ranges from a small fraction of one per cent. to more than 2.5 per cent. The present practice of "skimming" crude oil for gasoline makes it impossible for anyone to say how the gases of combustion from the delivered oil residues will analyze—the greater the percentage of volatile oils removed the higher the percentage of CO_2 from the residues will run.

Natural gas varies even more in composition and heat value than fuel oil. The values shown in the table will not, however, be far from the real facts in any natural gas field.

Before being able to say exactly how the gases of combustion should analyze, it is necessary to know how the fuel analyzes. The following table assumes averages of the respective fuels:

Fuel	% Theoretical CO_2	% Practical CO_2	% Air Excess
Anthracite	20.7	15.0	38
Bituminous Coal	17.9	14.0	28
Pulverized Coal	17.9	15.0	20
Sub-Bituminous or Lignite Coal			
Fuel Oil	15.0	14.0	7
Natural Gas	11.9	11.0	8
Wood	17.0	14.0	28
Bagasse	17.9	14.0	28
Gasoline	14.2	13 to 14	5
Kerosene	14.5	13 to 14	5

It is easier to mix air with gas than it is to mix it with coal unless the coal is crushed to an impalpable powder. These facts serve to explain the differences in temperature of the flue gases and the water in the boiler. If carried to such an extent that the gases are chilled below the ignition point, carbon (soot) is deposited on the metal surfaces of the boiler and the chimney smokes. Carbon which might otherwise have been burned, adding to the sensible heat of the gases, is lost. This soot also acts as an effective insulator, preventing the absorption of heat by the boiler surfaces. Too much excess air (faulty draft regulation) is by far the greatest cause of fuel waste.

What We Learn

Flue gas analysis "talks" in direct terms about combustion efficiency. The highest efficiency is attained when we get complete combustion with the minimum air supply. In doing this, we may get a temperature so high that the brick work of the furnace will be melted and the ash fused with the carbon to form a slag upon the grates. There are accordingly, limits to the CO_2 percentages which it is desirable to secure.

The most efficient percentage of CO_2—that is, the percentage of CO_2 that can be maintained without appreciable loss due to incomplete combustion—will vary: (a) With hydrogen carbon ratio; (b) the physical condition of the fuel, solid, liquid or gaseous; (c) the relation of volume of the combustion chamber to the grate area; (d) the method of firing; (e) the available draft, etc. But for every condition there is a percentage of CO_2 that will give maximum combustion efficiency for the conditions prevailing.

Flue gas analysis furnishes a check or measure on vitally important factors, which, while they cannot be observed with the naked eye, have considerable bearing on economy and efficient operation. There is a definite relation between the percentage of CO_2 in the flue gas and the chimney loss, hence the analysis of the flue gas for CO_2 offers a convenient and accurate gauge as to the quantity of air being used for combustion, thus enabling steps to be taken to maintain the best efficiency.

CO_2 and Efficiency

The apparatus which will constantly and accurately analyze the CO_2 in the flue gases and show the draft condition places in the hands of the boiler room operator the key to efficiency in his fuel consumption. All authorities agree on this point, that the CO_2 percentage is the index to furnace efficiency.

Combustion analysis tells us the efficiency of our boiler furnaces, neglecting the carbon that is being wasted with the ash and the heat that is being radiated from the furnace. It tells us whether there is combustible carbon monoxide passing off with the flue gases and how much, whether an excess of air is being taken, where the excess air is entering and what it amounts to.

It tells us what draft we should employ to insure the best efficiency, provided we have a draft gauge with which to measure the draft. The draft that goes with the desired percentage of CO_2 when the load is satisfactorily met, is the draft to be employed.

Applicable Anywhere

It makes no difference whether you are burning coal, wood, oil, tar, gas, tan, bark, bagasse or buffalo chips; whether it is a cook stove, a steam boiler furnace or an internal combustion engine. Use the right amount of air for combustion and you will get the highest efficiency. The percentage of CO_2 serves as a guide to show the ratio of the air taken for a useful purpose and the air excess that is taken for wasteful results. Learn what percentage of CO_2 there should be in the gases of combustion and make sure that you get it while avoiding CO. This is the beginning and the end of combustion efficiency. The details to be considered in working out your combustion problems will depend upon the fuel, the furnace or other contrivance in which the fuel is burned and the circumstances as to load, etc. Coal burns from the bottom up, sawdust burns from the top down. High volatile coals require an over-air supply as well as air under the grate. Gas, oil, and powdered coal should be mixed with air as far as possible prior to ignition. As you rise in the scale of fuels from lump anthracite to gas the air excess can be decreased.

Almost any question relating to economy in the combustion of fuel may be answered by flue-gas analysis when correctly interpreted. It indicates where,

Typical Modern Instrument.

Water Power Future in Austria

Possibilities for Economic Recovery in Dual Monarchy Despite Present Fuel Shortage

BY MAJOR D. H. PEARSON, F. R. ECON. S., F. R. C. I.

THE granting of a susbtantial loan to Austria has focused the attention of the business community on the possibilities for trade existing in that country and the difficulties with which the remnant of the great Austrian Empire has to contend

Economically, Austria is in a worse position than any of the former enemy countries; the important economic structure built up during the monarchy has come tumbling to the ground, shattered by the Treaty of St. Germain. Gone are the great industries, and seaports, the overseas trade; nothing is left but the skeleton of the industrial body of the former Empire.

Lack of Material

With such conditions it is difficult for the country to make a start, to get on its feet and to save what is left from complete commercial obliteration. It will be a long and laborious process, the more so as there seems no possibility of the country having its present boundaries extended to include some at least of the former districts in which industries thrived or from which raw materials for those industries were obtained.

Whatever the future may hold politically it is impossible to say; industrially, there may yet be a chance for Austria to recover now that outside financial help is forthcoming.

Coal Situation

The present Austria is deprived almost completely of fuel, without which it is obvious no industry is possible. According to the statistics of 1913, the last year of peace, the monthly requirements of coal amounted to more than a million tons, and of coke 110,000 tons. Against these normal requirements there is now an average coal production of about 240,000 tons a month in the Alpine provinces.

Only a very small quantity of this is black coal, the remainder being lignite of an even lower quality than North Bohemian brown coal. More than eighty per cent. of the coal requirements must be imported from foreign countries, to balance which there is practically nothing to export, The effect of these huge coal imports on the value of the crown is considerable. By eliminating them a sounder and more stable position would be attained.

Water Power Possibilities

There are, in the Alpine provinces, vast water-power potentialities, to the development of which more and more attention is being given. So long as coal and petroleum were available in practically unlimited quantities at comparatively low prices, such development did not offer enough profit on the great amount of capital necessary to finance the work.

Official reports on the water power sites in these provinces show that they total an amount of 1.7 million horse power, but these figures only take into account sites that yield at least 1,000 horse power mean yearly production.

Conservative estimates, taking into consideration all available sites, show that there are around three million horse power to be derived from water power works, and of this total two and one-quarter million horse power is regarded as easily capable of development. The present output of electrical energy from water power is small; on January 1st, 1920, the turbine output amounted to but 205,000 h.p. On the other hand the estimated requirements of electrical energy amounts to one million horse power. In other words, scarcely 10 per cent. of the water power available is at present utilized.

Development

There is some small development being carried out in the provinces, on the Grosse Muehl in Salzburg, in the Liechtensteinklamm, the Wiesthal and the Fuschertal, while small waterfalls are being used to provide power for farm purposes. The industrial district of Upper Styria, which is well within transmission distance of the great Styrian water power sites, would consume much electrical energy if it were cheaply produced, as it could be by water power.

Railway Electrification

Of the railways with a total length of about 6,000 kilometres, only one line of 63 km. and 15 local lines totalling 189 km. are operated electrically. For the next few years the electrification of main lines totalling 652 km. is proposed by the development of four water power sites.

The development of water power will mean much to Austria, and now that she has been granted an international loan such development is likely to be taken in hand to the ultimate benefit of the country and Canadian manufacturers.

Testing for flashpoint may be done in a simple manner by heating a few ounces of oil over a gas flame and trying a lighted match over the surface of the oil until a wave of flame can be seen to flash across its surface. The temperature of the oil when this takes place is called its flashpoint. Oils with specific gravities below 0.85 generally have flashpoints below 60 deg. Fahr. while those whose specific gravities exceed 0.85 have higher flashpoints.

Obituary

JOSEPH H. MacNeill, son of Archibald MacNeill, of Charlottetown, died at Irvington, New York, on April 18.

Mr. MacNeill was born at Charlottetown, Prince Edward Island, on Feb. 14, 1865. He was educated in the public schools and in Prince of Wales College. He was connected with the Prince Edward Island Railway in early life, both in a mechanical and executive capacity. He held the position of chief engineer of ocean-going vessels under licenses both from the United States government and from the British Board of Trade and for several years was an engineer officer of the Eastern Steamship Company, sailing out of the Port of Boston.

Later, Mr. MacNeill was engineer of the New England Piano Company at Cambridge, and of the Hood Rubber Company at Watertown, Mass. He left the latter position in 1898 to enter the service of the State of Massachusetts as a boiler inspector. About ten years later he became chief inspector and chairman of the Massachusetts Board of Boiler Rules. In both capacities he had much influence in shaping the laws and rules governing the construction, installation and operation of boilers in the East.

Mr. MacNeill resigned from the Massachusetts State Inspection Department on July 8, 1912, to take the position of chief inspector of the Boston Department of the Hartford Steam Boiler Inspection and Insurance Company, and at once entered on the duties of that new position. He remained in Boston until May, 1915, when he was transferred to the New York office of the company, where as chief inspector, he continued until his death to have charge for the company of inspection work in the State of New York and sections of Vermont and New Jersey.

* * * *

Canadian manufacturing and financial circles are the loser by the death in London, Ont., on April 20, of Frank E. Leonard, president of E. Leonard and Sons. The death of Mr. Leonard followed a short illness and was entirely unexpected by his many friends and associates.

During his connection with the Leonard Co., manufacturers of boilers in Canada for over 86 years, Mr. Leonard became associated with a number of enterprises. He was a director of the Huron & Erie Mortgage Corporation, and of the Canada Trust Co. and was a past president of the old London Board of Trade.

Mr. Leonard was a life long resident of London, having been born there 70 years ago. By strict adherence to the best principles of business he established an enviable reputation in the industry and his many friends share the sorrow at his passing

Editorial Comment

CAMPBELL BRADSHAW, Editor

Rule of Thumb Deadly

CONSISTENCY of the stick-in-the-mud routine type is the hobgoblin of small minds for there are few things more irritating than the human machine, the flesh and blood automaton.

When consistency is interpreted to mean the submerging of initiative to make room for phlegmatic living, the word has lost its worth.

It does everyone good to depart occasionally from the beaten path to take part in the unusual.

Medical men vouch for the beneficial effect of temporary relaxation or deviation from routine to something unorthodox.

Charles Dickens makes one feel tenderly sympathetic in "A Christmas Carol" when Scrooge magnanimously allows his office clerk Christmas day away from the "tank" where in a terrible monotony he had labored on a shiny high stool month after month.

While all who toil in the power plant field stage essentially alike repetition of their tasks, engineers are to be envied, who, in leisure time, throw off the restraint of routine and, according to mood and temperament, follow the example of the members of Canada Council No. 27 of the Universal Craftsmen at their anniversary banquet a few days ago.

The most helpful friends an engineer can have are those engaged in his own vocation and beyond question the best place for him to meet friends of this sort is at meetings of organizations such as the U. C. C. of E. and the C. A. S. E.

If the hundred engineers present at the festivities in the Oddfellows Temple in Toronto left the banquet table without either adding to their store of knowledge or gaining inspiration for the task of the to-morrow, they at least were enriched by the friendships they renewed and by the spirit of goodwill to all men which pervaded the building for six hours.

At the annual convention of the Canadian Association of Stationary Engineers in the Central Technical School, Toronto, June 25, 26, 27 and 28, another opportunity will be given engineers to enjoy complete relaxation by meeting hundreds of their fellows who consider interest and application not only necessary to progress but as putting a more attractive complexion on the day's work. It must not be forgotten that although engineers and firemen work methodically and systematically to keep the steam at the required pressure with a minimum of expense, if they play systematically, read according to discipline, and use their leisure time to the beat of a pendulum, they "stunt" the essentials of life.

When the hobgoblin of a mistaken consistency settles on their shoulders they write on their own tombstone the inscription: "Died for want of a change."

How to Bribe Engineers

RATHER a surprising title, that—and one that does not, seemingly, inspire confidence.

Graft is much talked about these days—so often played up in newspapers and magazines with black or red "streamers," reeking with cheap sensationalism—that engineers as well as business men are peculiarly sensitive about their reputations.

"Where will exposure strike next?" has become a by-word in the field of human endeavor, so many unexpected instances of graft have been brought to light—cases where men in the business world supposedly of the highest ideals leaned and bent under the sudden pressure of unusual misfortune and went down in the wreck, wrecked in reputation as well as finances.

If the business world loves success and abhors failure, at least the business world respects honest failure and so not withstanding all this talk of graft the majority of honest workers is so large—so much greater than the grafters, that the latter class dwindles to a very small percentage.

In no profession is honesty more marked than in that of engineering. In no profession can more honest integrity and less liability to lean toward dishonest practices be found.

Yet, there are ways in which an engineer may be bribed. Be he little or big, every man has his price—and engineers are no more exempt than others.

How, then, can an engineer be bribed? If he is honest how can he be approached and induced to throw his influence toward the installation of certain equipment, for example?

The field representatives of every firm can exert personality—limited or unlimited—according to the amount of their influence and the range of its power. Every engineer is more or less affected by the influence brought to bear upon him by the men with whom he comes in contact. He likes to purchase or recommend the purchase of apparatus known to be efficient and reliable and as a result he often places orders right over the heads of less recommendable manufacturers though the latter may be lower in price—simply because he "likes" this packing or "dislikes" that valve, so it remains for the wise manufacturer to make his product "liked."

How can he do this?

First, get a reputation for good service; have the news spread broadcast that the equipment in question never causes annoyance—but always works efficiently without friction.

This is easier to do than one realizes, for reputation is the widest circulating wireless intelligence in the world.

The manufacturer who wants to influence engineers his way must pry his way instead of pushing. Let him quietly, calmly keep in touch with the men he wants to do business with, taking every opportunity to pound home the idea that he knows his business, that his product can do the work claimed for it and that it can be depended upon to give long and efficient service.

Such a man will always get the business because his product will always be "liked."

You can't bribe a Canadian engineer with money, but you can influence him by good service, dependable business methods and the sheer worth of your product.

Free But Not Cheap

EVERY fireman is aware that less than twenty tons of air will fully burn a ton of coal, but since no trust has as yet monopolized the freedom of our Dominion air, his fire-holes, all yawning wide, admit great chunks of atmosphere.

If some method could be determined to bottle up this air, and make the owner of each boiler pay a yearly rental to get his share a lot of careless operators would soon realize that a thing's not always cheap because it's free!

Practical Ideas From Practical Men

STEAM TIGHT GASKETS

*By James E. Noble

The article "Practical Gasket Hints" on page 31 of the April 5th issue of Power House, contains several inferences which in my estimation are not correct.

The writer of the article has had 10 years experience with gaskets, but as my experience is over 25 years while acting as chief engineer in several large plants, there is little egotism in my belief that I am entitled to give my ideas upon the subject.

Experience has convinced me that the thinner a sheet rubber or combination rubber and asbestos or some other material is at the final tightening of the bolt nuts, the longer it will remain steam tight under expansion, contraction and other strains.

I believe Mr. Bohner is mistaken when he states that wrenches, such as spanners are generally made the proper length. It is possible to purchase wrenches to fit 1¼ inch bolt nuts with handles from nine to twenty-four inches long.

Job for Sandow

It would require a Sandow using a wrench with a nine inch handle to exert enough pressure on a 1¼ inch bolt nut to make a satisfactory job in a number of different locations where such sized bolts are used.

It is not bad practice to use an extension handle 6 or 8 inches long on a short handle wrench when tightening large bolt nuts.

A steam line which has to depend upon the expansion and contraction possibilities of the flange gaskets to take care of all the movement of the pipe with no use of expansion joints, bends or other provision, would have small prospect of remaining steam tight or in safe condition.

Doubts Claim Made

The writer of "Practical Gasket Hints" claims he knows of many cases where thick flexible gaskets have taken care of all the expansion in ordinary saturated steam carrying lines. I confess I have never seen such a case in my experience outside of a line a few feet long; the lineal expansion on such a stem line will approximate two inches to the hundred feet. How is it possible for gaskets to take up this amount of movement?

I have made hundreds of permanently steam tight flange joints on lines where the steam supply was being constantly turned on and off and where the temperature in the rooms containing the joints constantly varied. The material I used was common 1-32 inch thick sheet asbestos.

Advises Great Care

The special method I am describing is to be used on flanges in a horizontal position whenever possible, great care being necessary when the flange faces are vertical. Carefully clean the flange faces, cut a round gasket the size required from the one thirty second inch sheet asbestos, cut out the center and bolt holes, separate the flanges, coat the face of the bottom one with clean thin liquid shellac. Place the asbestos gasket upon it and after pressing it down all around allow it to set a few minutes then thoroughly saturate the asbestos with water, next carefully bring the flange faces together being careful not to tear the wet asbestos. Place the bolts and tighten up as tight as good practice allows, then turn in enough steam to dry out the gasket before you give it full pressure and you will have a joint that will not leak as long as the bolts or nuts are not disturbed.

Heat Without Effect

Expansion and contraction or varying outside temperatures will have no effect upon it if the work has been done right. It is of course absolutely necessary to have the flange faces clean and in proper alignment.

A number of years ago when employed as repair man with the Canadian General Electric Co., at Peterboro, Ont., I connected the two halves of a heavy cast iron steam table, practically a pair of flanges, only much more complicated in design, over 30 bolts being used in holding the halves together. The bearing surfaces were narrow and long with channels between for the steam to travel through as it was necessary to have the whole of the table surface of 8 square feet at a uniform temperature.

A Steam Tight Job

I succeeded in making a permanent steam tight job using the method I have just described, although several other methods had been tried out without success.

The wet sheet asbestos joint comes close to an iron to iron one, as the thin wet sheet will compress to almost the vanishing point, and despite conflicting opinions as regards a compressed joint expanding, contracting, and leaking, I will guarantee any engineer will not find things so if he uses the method I have described.

---

*173 Macdonell Ave., Toronto, Ont.

In placing rubber packing joints together, use either graphite or chalk to prevent the rubber adhering to the metal when the joint is to be broken.

MOTORS IN DAMP

*By W. MacKenzie

Motors that drive various forms of mechanical equipment used in a modern pulp and paper mill, operate in the majority of cases, under conditions which are so very severe as to constitute a most rigid test of the insulating materials used in their construction.

Moisture and acid fumes are of course the cause of most of the motor troubles, and due to the large amounts of steam and water used for heating, washing and other purposes, the air is always saturated with moisture.

The maintenance and repair problems which are thus presented are further complicated by the fact that anything more than momentary interruption cannot be tolerated. Continuity of service must be maintained at any cost. We have developed, on completely rewound motors and generators, a special insulation and varnish treatment that has given excellent satisfaction in several of the pulp and paper mills of the Niagara district.

After the stator coil loop is wound, metal clips are put on the sides to hold the wires in place; the loop is then dipped in a special acid and moisture proof varnish and allowed to soak until no more air bubbles are given off. The loop is then allowed to drip until all excess varnish has run off and then baked for 10 to 12 hours in an electrical oven.

Following this, the loop is pulled to shape in a special machine, insulated with high grade varnished cambric and cotton tape, and the complete coil again dipped in varnish, allowed to drip and then baked for 20 to 24 hours at an approximate temperature of 100 deg. Centigrade.

The next operation is to wind these coils in the stator. After connections are made, the high potential ground and between phase test is applied for one minute. If the test is satisfactory, the stator is placed in the oven and baked for 10 hours and then immersed completely in a large dipping tank while still hot, allowed to drip and then again baked for 12 to 15 hours.

TURBINE BLADING

*By J. W. Carruthers

Some time ago an article appeared in Power House on the operating methods employed in a certain power plant, and the different instruments and charts used were explained at length.

One paragraph, in relation to the steam flow to turbines, said: "That information relative to the condition of the blading is obtained by the indication of high or low ratios." It therefore occurred to the writer that some indication of what is going on inside the turbine would be very desirable before the steam consumption indicated that the blading was beginning to go. The writer remembers being carefully instructed by turbine experts in a large factory of the necessity of periodically making certain tests to obtain this information.

---

*Engineer, The Acadia Coal Co., Stellarton, N.S.

It might be remembered that a turbine is a heat engine, therefore a test taken on a thermal basis is a measure of its efficiency as a heat engine. If certain precautions are taken anyone may make such a test, and get at least an approximate idea of the condition of the blading. If such a test were taken say, when the machine is new, then any subsequent test would reveal valuable information. If the temperatures of the steam are taken at the throttle, 1st stage, and entering the condenser, the ratio of these readings is an approximate value of the efficiency of the machine, and any dropping of this efficiency, assuming that the other items had been carefully noted, would indicate that the blading was beginning to go, and incidentally the steam consumption would gradually go up.

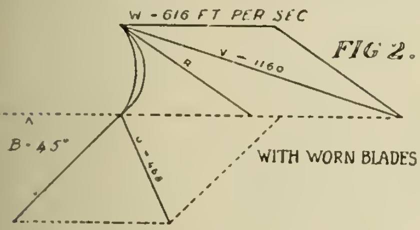

FIG 2.

Must Measure Pressure

With saturated steam the above test would probably be correct, but when using super-heated steam the pressures would have to be measured to find the total heat contents of the steam. Conditions of load, vacuum, barometer, would have to be the same, or corrections made when taking a comparative test such as the above. It might be interesting to go a step further and explain why it is that worn or broken blading increases steam consumption.

To many of the readers of Power House this would not be a very difficult matter, and they would probably make a better job of it than the writer, but in the interests of the many young engineers, and without going too deeply into intricate formula, it is believed that the following explanation will lay bare the reasons for the higher consumption of steam due to worn or damaged blading.

It is well known to all "rotary" men that the blades of an impulse turbine have the "entrance" and "exit" angles equal, the reason for that is, that there is no great thrust to be taken care of, because the re-action of the jet leaving the blading is balanced by the impulse of the jet entering the blading.

This can best be shown graphically or vectorially as it is sometimes called. To clearly show the action of the steam on the blading involves a discussion of certain angles and their reciprocals. The most important of these is the statement that in any triangle the square of any side is equal to the sum of the squares of the other two sides, minus twice their product into the cosine of their included angle.

Proof Unnecessary

Trigonometrical proof of this statement is unnecessary and would take too much space. Figures are more interesting to the average engineer, and more convincing. We will, of course, have to refer to a table of trigonometrical functions for the values of the angles under discussion. Before going further it must be borne in mind that the energy of 1 lb. of steam impinging against the turbine blades is

$$\frac{V^2}{2g}$$

and of 1 lb. as it leaves the blades is

$$\frac{v^2}{2g}$$

The energy of the vane is therefore

$$\frac{V^2—v^2}{2g}$$

and by the principle of machines the efficiency will be:

$$E = \frac{\text{Energy absorbed by blades}}{\text{Total energy delivered to blades.}}$$

The 2g cancelling out in each case so that the velocities need only be considered. Supposing then that we have the conditions illustrated by Fig. 1. Our load we will say is 1,500 kw. and we know that under our operating conditions our water rate is 14 lbs. per kw. This gives us a total weight of steam of 21,000 lbs. Now $V=\sqrt{2g} \times \sqrt{21{,}000}=1160$ ft. per second.

That is, the velocity of our steam is approximately 1,160 ft. per second with the other values essentially as shown in the sketch. That is, the initial angle A is 20°. The angle C is made twice the value of A because according to the best authorities of blade design, this gives the condition of highest efficiency. And B (final angle) which is equal to C to make the blade symmetrical, is also 40°. The value of W (speed and direction of blade) and hence of R. can be calculated by this formula:

$$W=\frac{V}{2 \cos A} \therefore W=\frac{1{,}160}{2 \text{ x}.94}=616 \text{ ft.}$$

per sec. .94 is the cosine of the angle A=20°. The final absolute velocity is calculated by $v=w\sqrt{2}$ (1 cos. B) $\therefore$ $v=616\sqrt{2}$ x .234=132 ft. per sec.

And the efficiency of such blading in good condition would be

$$E=\frac{1160^2—132^2}{1160^2}=90\%$$

approximately.

When Wear Appears

But now let us go further and try and find out what would be the condition of the above machine, supposing that the blading was beginning to show signs of wear. We will perhaps find that the blading is worn away quite a bit where the steam leaves the wheel, or in other words, that the final angle has become greater than formerly. We will suppose, then, that the final angle B, instead of being 40° is now 45° as in Fig. 2 owing to the wearing away of the blading. We will insert this value into our formula and we find the following:

$v=w\sqrt{2}$ (1 cos. B) $\therefore$ $v=616\sqrt{(2\text{x}.707)}$ $=468$ ft. per second, instead of 132 ft. per second, which was the value when the blades were in good condition, and it can be shown that the efficiency now is

$$\frac{1160^2—468^2}{1160^2}=80\%$$

with the blading in bad condition.

It is obvious that to obtain high efficiency the final velocity (v) of the steam must be small as otherwise energy would be wasted without doing work on the blading of the machine.

The deterioration of turbine blading has always been an interesting subject for turbine engineers. No successful means has yet been found to stop this action. Various theories have been put forth as to the cause of it, but we are still looking for a metal for our blading which will not be affected by the severe conditions which obtain in actual practice.

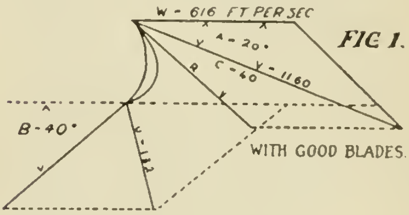

FIG 1.

Causes of Corrosion

Some of the causes of the corrosion of turbine blading are interesting. Some engineers say that critical conditions as regards temperature, pressures, loads and speed cause the blades to go. Others say that organic matter carried over with the steam may cause chemical action on the blades. In this connection Sir A. C. Parsons a number of years ago suggested that strainers made of the same metal as that of which the blading was composed, should be inserted in the steam pipe near the throttle. The idea, it is presumed, being that the chemical action would be confined to this strainer, and so save the blading. How far this may have been successful there is no data yet to hand, at least the writer has not heard of any. In our opinion the most prevalent initial cause is steam leaking through the blading of machines while they are standing idle.

The majority of engineers know of the great difficulty there is in keeping valves tight where super-heated steam is used. After trying various makes of valves and seats, which may be all right for a short time, eventually the leaking steam again makes its appearance and finds its way through the blading of the turbine with the usual result.

In this connection, some years ago, the

writer suggested that the steam pipe to the turbine be drained to a trap and taken back to the feed water heater, this drain being kept open when the machine was standing idle.

The leaking steam would then take the easiest path in preference to the more tortuous path through the blading of the machine. Recently this has been done in our own plant, but the good results which we anticipated from this alteration will not be apparent until a certain length of time has elapsed.

Follow Leaking Steam

If we follow this leaking steam with its alleged metal attacking properties, it will eventually find its way to the condenser, and here an interesting state of affairs appears to exist, which, I am afraid, will take an abler pen than mine to describe.

Here we have on one side of the tubes a vapor which is supposed to have an affinity for certain metals, and on the other side of the same tubes we have perhaps salty water, which also has the same properties, and the result is, we say perhaps, condenser tube corrosion. We have a pet theory of our own which may help to explain blade corrosion from this point, but of that, as the dramatists say, "More anon."

The writer of these notes hopes that they may prove interesting to engineers who are in daily touch with this class of work. The samples given are purely hypothetical and are not intended to refer to any particular condition, but they probably are what would obtain in a medium sized plant. There are, I know, many engineers who know this subject thoroughly, and the data given may appear to them to be "old stuff." This article is intended, however, for the young fellow who is probably just looking for something along these lines to help him out in his own plant, and if the writer has succeeded in giving him a new angle on the subject, the object of the article will have been fulfilled.

BOILER FEED PIPING

By Robert Larsen

While the general principle of a feed water layout is the same regardless of the size of the plant, the introduction of heaters, condensers, hot-wells, pumps, traps and injectors complicates the matter to such an extent that the necessary details are often confusing. It is proposed in the present article to give a couple of diagrams covering the usual conditions, together with rules for determining pipe sizes, and other practical data relating to the subject.

It is always important for the engineer to know something of what lies beyond the opening with which he connects a pipe, and for this reason a little time has been devoted to the internal feed arrangements and the conditions necessary for introducing water without damage to the boiler.

Feed Piping Divided

Feed piping may, in a general way, be divided into two parts, **internal** and **external**. The first of these includes that portion within the boiler shell, and its construction is of great importance, both as regards safety and also efficiency of operation. The conditions sought in the design and construction of internal feed pipes are, first, to raise the temperature of the entering feed water as nearly as possible to that of the contents of the boiler; second, to discharge it so as to assist and not retard the natural circulation; and third, to avoid directing it so as to impinge at once upon the hot plates of the shell, drums or tubes.

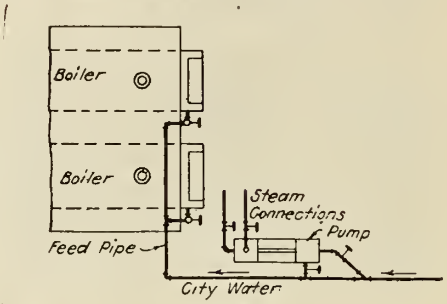

Fig. 1

The older practice of feeding boilers at the bottom, either through the blow-off pipe or by means of special connections, has now been practically done away with in new installations. The only condition where this should ever be considered is in the case of low-pressure heating boilers where the condensation is returned at a fairly high temperature and where there is a tendency for the blow-off pipe to become clogged with sediment. Even in cases of this kind it is generally considered better practice to provide a circulation pipe in connection with the blow-off and admit the feed water through a special connection properly located.

The water fed into a boiler is always colder than that already inside, the difference running all the way up to 100 degrees or more, depending upon the pressure carried and the conditions of operation.

How to Supply Water

Water at lower temperature introduced at bottom of boiler cannot rise with the natural circulation until it is sufficiently heated to reduce its density to that with which it is surrounded. From this it is evident that the feed water must first spread out on the lowest part of the boiler surface while being heated to the necessary temperature for circulation. This naturally cools the plates and sets up strains which are much larger than is commonly supposed.

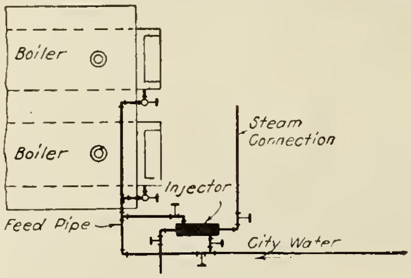

Fig. 2

As the rapidity of heat transfer from the metal to the water depends upon the temperature difference, it is evident that the cooler the water the more rapid will be the cooling effect. The amount of cooling for a given weight of water is proportionately large because it takes much more heat to raise the temperature of one pound of water 1 degree than is given up by the cooling of a pound of steel or iron through a like temperature range.

Furthermore, since the heating is so rapid, by far the greater portion of the heat given to the cold feed must come from the store of heat already in the metal and not from the heat transferred from the furnace gases through the shell or tubes. Hence, the plates are cooled through a considerable range of temperature with each admission of fresh feed water.

Personals

George W. Beardmore, president, Beardmore Belting Co., 37 Front Street East, Toronto, is seriously ill with pneumonia. Mr. Beardmore is known nation wide as one of the most prominent manufacturers of belting.

H. J. Heasley, sales manager for Sadler & Haworth of Montreal, has just returned from an extensive trip throughout the Canadian West. Mr. Heasley found business conditions are showing a decided improvement over last year.

Geo. Callard, builder and contractor, of Montreal who is well known throughout the province as a specialist in furnace and boiler settings is ill at the Royal Victoria Hospital, Montreal. It will probably be several weeks before Mr. Callard will be able to resume business.

Wm. Carter, assistant general sales manager, Canadian Ingersoll-Rand Co., Montreal, was a visitor at the Industrial Paper Show in New York. The above company in association with their American principals had a booth at the show, showing pulp mill machinery.

Hamilton Chamber of Commerce held its election of officers last week, and the following have been appointed to the executive: W. H. Cooper, president; W. J. Westaway, first vice.; George R. Kerr, second vice.; E. V. Illsey, treasurer; Benson Johnston, chairman of committee on committees, and G. E. F. Smith, chairman, finance committee.

M. L. (Bob) Kane, manager for the past six years of the gas department of the Winnipeg Electric Railway has left to assume the management of the gas business of the Georgia Railway and Power Company at Atlanta. Prior to coming to Winnipeg in 1917, Mr. Kane, was in charge of the gas department of of the Continental Gas and Electric Corporation at Cleveland. On the occasion of his departure from Winnipeg he was the recipient of several valuable gifts, both from his associates in the company and from his many friends in the clubs to which he belonged.

Odd Questions and Their Answers

Queries are invited on the every-day problems of engineers in all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped a fellow engineer and a pleasure for us to pass on the data.

POWER TO PUMP WATER

There are two methods of figuring the power required to pump a given amount of water per minute against a stated head or pressure. The first of these is based on the weight of water discharged per minute and the head pumped against.

If the water is merely drawn from one open tank and pumped into another open tank at a higher level through piping without appreciable friction, the head is the difference in level of the water in the two tanks. Where there is a pressure gauge just beyond the pump discharge, the head in feet at that point is equal to the reading of the gauge in pounds per square inch multiplied by 2.3. To this should be added the distance in feet from the center of this gauge down to the level of the suction water. Where the suction water is at a higher level than the pressure gauge, this difference in elevation is subtracted. The total head and weight of water discharged per minute being known, the horsepower is figured in the manner illustrated by the following example:

Suppose that 2,000 lb. of water per minute is being delivered against a total head of 50 ft. The net work done per minute is 2,000 × 50 = 100,000 foot-pounds.

Since one horsepower is equal to 33,000 ft.-lb. per min., the theoretical power required is equal to 100,000 ÷ 33 000 = 3.03 h. p. This is the power that would be required by a perfect pump. If the pump used has an efficiency of 60 per cent., the actual power required will be equal to 3.03 ÷ 0.60 = 5.05 horsepower.

Another way to figure the work done in pumping water is to multiply the cubic feet of water delivered by the total pressure worked against in pounds per square foot. If the total head in feet has already been figured as previously described, it can be reduced to pounds per square foot pressure by multiplying by 62.4, the weight of a cubic foot of water. On the other hand, pressure in pounds per square inch may be changed to pounds per square foot by multiplying by 144, since there are 144 sq. in. in one square foot.

Suppose, for example, that a pump works with an inlet suction of 2 lb. per sq. in. and a discharge pressure of 70 lb. per sq. in., the inlet and discharge being on the same level. Then the total pressure worked against is 72 lb. per sq. in or 72 × 144 = 10.368 lb. per sq. ft. If the discharge is 40 cu. ft. per min. the theoretical power will be

$$\frac{40 \times 10{,}368}{33{,}000} = 12.6 \text{ h. p.}$$

* * * *

BOILER INTERIOR

When setting the interior of a boiler what are the most common defects to look for?

Answer:—Corrosion and pitting at the water-line, grooving at the seams, loose stays and braces and thin plates, using the hammer test to detect the last two, also see that the feed pipe and dry pipe are secure.

* * * *

CROSS-EXHAUSTS

What is the real purpose of the so-called cross-exhaust connection in compound direct-acting steam pumps?

Answer:—The purpose of the cross-exhaust is to maintain a more uniform pressure in the low pressure steam chests; without its use there is a diminishing pressure in the L. P. steam chest as the piston moves along, creating a tendency to short stroke; the purpose of cross exhaust connection, is to admit exhaust steam from the opposite side of the pump at the correct time, thus forcing the piston the full length of its stroke.

* * * *

GENERATOR POWER NEEDS

Can you tell me what power must be developed by a direct-connected engine to run an electric generator so that it will develop 85 electrical horse power?

Answer:—The indicated horsepower required to be developed by the engine would depend on the efficiency of the generator and the engine. The efficiency of the generator would be about 90 per cent. and the mechanical efficiency of a suitable engine would be about 88 per cent., and therefore an engine suitable for the purpose would be required to develop about 85 ÷ (0.90 × 0.88) = 107.3 indicated horsepower.

* * * *

LEAKY TUBES

I am handfiring a return tubular boiler that gives much trouble from leakage around the tube ends when I use soft coal although there is little leakage when firing hard coal. How can this condition be remedied.

Answer:—The trouble when burning soft coal undoubtedly results from incompletion of combustion before the gases reach the back connection of the combustion chamber, due to insufficient height of the boilers above the grates. Better results would be obtained by having the boilers set higher above the grates and by firing lighter and oftener. If the tube ends are beaded over, they will be better protected from fire.

* * * *

BELT TROUBLE

Why does a belt always run to the outside of a 2 in. pulley on two shafts running parallel to each other and about four feet apart. The pulleys are of wood, with a flat surface and the belt generally overlaps the pulleys about half an inch? T. G. Lowe, Winnipeg.

Answer: It would appear that your chief trouble lies in the alignment of the two shafts on which the pulleys are mounted. This should be checked by means of a straight edge, placed alongside the pulley edges and should touch the two pulleys at four points, that is, the rim and centre of each. If the shafts are not in alignment, nothing can be done to prevent belts running off.

If, however, the shafts are properly aligned and the trouble still occurs, it is in all probability in the pulley faces. If the face of the pulley is perfectly flat, as you say, it would seem that the belt is slipping over until the pulley edge is used for a crown.

Check the pulley faces by means of a steel straight edge. If this is the case, the only solution is the replacement of the pulleys by a set with a properly crowned surface.

* * * *

DIFFERENT ELEVATIONS

A condensing-steam power plant at sea level is a duplicate of one installed on a mountain. Both plants are operated with steam at 150 lb. boiler pressure and carry the same load. The vacuum at the sea-level plant is 28½ in., while that at the other is 27½ in. Which plant should operate with better steam economy?

Answer:—The absolute pressure in a condenser, expressed in inches of mercury, is the difference between the barometer of the place and the number of inches of vacuum. Hence if the same difference were 1 in., the absolute back pressure in the condensers would be 1 in. of mercury column pressure in each instance. However, as the absolute initial pressure of the steam is gauge pressure plus the pressure of the atmosphere at the place, the plant at sea level is operated from a slightly higher absolute pressure. But the greater amount of work available would be less than 1/10 of 1 per cent. and therefore, for all practical purposes, the steam economy of the plants should be the same.

* * * *

PHASE AND CYCLE

Will you explain the terms, "cycle" and "phase" in connection with a D. C. Generator. W. R. E.

Answer: These terms have no application in discussing D. C. generators or circuits, but are applied to A. C. only. In reference to an Alternator, a cycle is the building up of the current from zero to maximum strength, returning to zero, and then going through the same procedure in the opposite direction. By phase, is meant the angle turned through by the armature, reckoning from a given instant. Various types of alternating current are known as single phase, two phase, three phase, etc.

* * * *

STEAM EXPANSION

A steam-engine cylinder is 33⅛ in. diameter, and the piston has a stroke of 3 ft. 3 in. The engine develops 600 I. H. P. at 100 revs. per min. Assuming a diagram factor of 0.82, what is the ratio of expansion if the initial steam pressure is 155 lb. per sq. in. absolute, and the back pressure 21 lb. per sq. in. absolute? (2) In a turbine the nozzles are inclined at 20 de. to plane of rotation, and the velocity of the blades is 400-ft./sec. There are three rings of rotating blades and two fixed blades. Determine the angles of the blades and work done per pound of steam, assuming the velocity of the steam leaving the nozzles is 2,800-ft./sec.—V. B.

Answer:—Let R be the ratio of expansion required; pm the mean effective pressure; p_1 the initial pressure; p_2 the back pressure; and c the diagram factor. Then—

$$\text{pm} = c\left\{p_1 \frac{(1 + \log^{\epsilon} R)}{R} - p_2\right\}$$

—i e.,

$$\text{pm} = 0.82\left\{155 \frac{(1 + \log^{\epsilon} R)}{R} - p_2\right\}$$

$$= 127\left(\frac{1 + \log^{\epsilon} R}{R}\right) - 1.64 \ldots.(1)$$

Also— $$\text{H. P.} = \frac{\text{pm l A n}}{33{,}000},$$

where l, A, and n have their usual significance, That is—

$$\text{pm} = \frac{33{,}000 \times 60}{3.25 \times 0.785 \times 33.125^2 \times 200}$$

$$= 35.38 \text{ lb. per sq. in.} \ldots\ldots\ldots (2)$$

Thus expressions (1) and (2) must be equal.

$$\therefore 127\left(\frac{1 + \log^{\epsilon} R}{R}\right) - 1.64 = 35.38$$

—i e., $$127 \frac{(1 + \log^{\epsilon} R)}{R} \times 37.02;$$

or, $$1 \log^{\epsilon} R = 0.292 R$$

—i.e., $$0.292 R - \log^{\epsilon} R - 1 = 0.$$

This equation can be solved by giving R various values and evaluating the left-hand side. The best method of doing this is to tabulate as follows:—

R.	0.292R.	Log^ε	Y.
5	1.460	1.6077	— 1.1477
6	1.752	1.7899	— 1.0379
8	2.336	2.0771	— 0.7411
10	2.92	2.3	— 0.38
12	3.504	2.482	+ 0.024
14	4.088	2.366	+ 0.452

$$Y = 0.292 R - \log^{\epsilon} R - 1.$$

Plot the values of R and Y on squared paper (see Fig. 1). The value of R when Y=0 can be read off the graph fairly accurately. The writer's value, obtained in this way, is—

$$R = 11.85$$

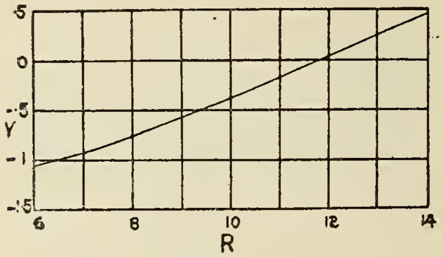

FIG. 1

To determine the angles of the turbine blades, proceed as follows: Referring to Fig. 2, set out V equal to the speed of the steam leaving the nozzles, and making an angle of 20 deg. with U, the direction and speed blades. Complete the triangle by drawing R, the speed of the steam relative to the blades. Then the angle between R and the horizontal is the angle of entry for the first set of moving blades. This is 23 deg. These blades are usually made symmetrical, so that the angle of exit is also 23 deg. Neglecting friction, the speed of the steam relative to the blades will be the same at exit as at entry. Thus make R_1 = R, and let it make an angle of 23 deg. with the horizontal. Combining R_1 with U, we obtain A, the absolute velocity of the steam as it leaves the first ring of moving blades. Thus the angle made by A with the horizontal is the angle of entry for the first ring of fixed blades. This is 27.2 deg. As the blades are symmetrical, this is also the angle of exit for the first ring of fixed blades. The other angles required are obtained in the same way, and are—

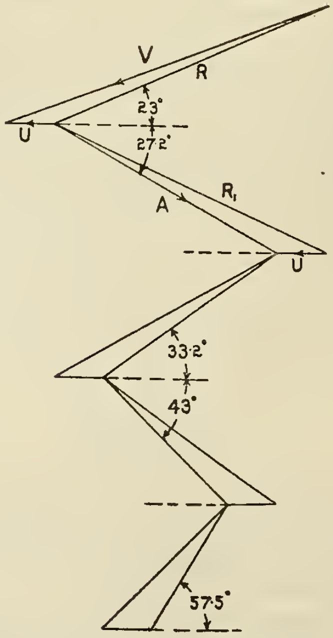

FIG. 2

Angle for second ring of moving blades = 33.2 deg.

Angle for second ring of fixed blades = 43 deg.

Angle for third ring of moving blades = 57.5 deg.

The work done per pound of steam entering per second for first ring

$$= \frac{1 \times 2}{g} (V \cos 20 \text{ deg.} - U)\, U$$

$$= \frac{2\,U}{g} R \cos 23 \text{ deg.}$$

$$= \frac{2\,U}{g} \times 2231 \text{ ft.-lb.}$$

Similarly, for second ring, work done

$$= \frac{2\,U}{g} \times 1737 \cos 33.2 \text{ deg.}$$

$$= \frac{2\,U}{g} \times 1452;$$

and for the third ring, work done

$$= \frac{2\,U}{g} \times 638.$$

Therefore total work done per second per pound of steam

$$= \frac{2\,U}{g} \times 4320$$

$$= \frac{800}{32\,2} \times 4320$$

$$= 107\,500 \text{ ft.-lb.}$$

In practice the friction of the steam on the blades causes a modification of the relative velocity of the steam such that R_1 would probably be equal to only 0.9 R, and so on throughout the calculation.

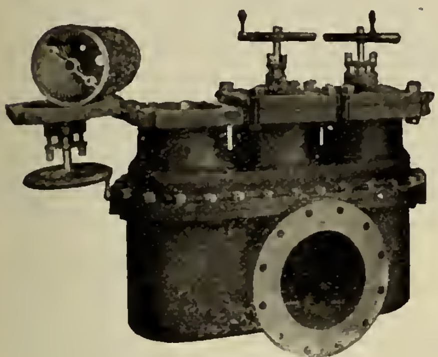
Trade Catalogs

Republic Flow Meters Co. has issued a 16-page bulletin which is entitled "Operation and Construction of the Republic Flow Meter."

Westinghouse Electric & Mfg. Co., has issued leaflet 1867, which describes electrical equipment for coke plant machinery.

We Supply
Automatic Water Softeners

For the purpose of removing by chemical means the scale-forming matter from water.



Three Basket Filter

These filters have from one to six baskets and can be arranged to remove foreign matter to any degree of fineness.

Lagonda Water Driven Cleaner for Curved Tubes

Lagonda Air Driven Cleaner for Straight Water Tubes

Cleaner Removing Scale from Outside of Fire Tube

ALL natural waters contain some impurities, which, when introduced into a boiler, may appear as solids deposited on the heating surface. No matter what the substance consists of, it must be removed at frequent intervals or it will decrease the capacity and efficiency of the boiler and may cause it to be badly damaged by over-heating.

Some waters, notably well waters, deposit such quantities of scale that it should be purified before going into the boiler, thereby preventing an accumulation of incrustation and consequent damage to boiler parts, and at the same time effecting a large saving in fuel by keeping all parts of the heating surface in a clean and efficient condition. If you have bad feed water it is a case for the chemist, for the scale is probably composed of several substances which must be known before the exact treatments necessary to get rid of them can be determined upon. The use of treatment without technical advice is poor policy.

Stony and vegetable matter in suspension can be removed by FILTERS, which we supply in various sizes and designs to suit all requirements. In most Canadian plants, lake or river water is used for feed, and these waters seldom carry large quantities of scale-forming materials in solution. Scale can be allowed to form in the boiler for a considerable period. Experience in each individual plant determines the limit at which tube difficulties will begin or a perceptible falling off in efficiency will take place. With such a limit of scale formation fixed, and the danger of allowing it to be exceeded, well understood, probably the most economical and efficient method of keeping the heating surfaces clean is by the use of the LAGONDA TUBE CLEANERS.

The cleaners are designed and so constructed as to thoroughly remove all the scale, in the shortest possible time, at the lowest cost of operation, and they require a minimum amount of repairs, reducing both the waste boiler time and labor cost of cleaning.

They are made to operate by either water, air or steam, and electricity. In every case a swing head is furnished so designed that three sets of cutters are thrown out by centrifugal force against the scale in such a manner that they make straight line contact with the tube and they do the work without damage to it.

You can be supplied with LAGONDA tools for cleaning Economizers, Condensers, Evaporators and other tubular plant.

Catalog and full particulars for the asking.

Progress in New Power Equipment

METHODS OF REMOVING SOOT

Engineers who are delving into new methods of doing work around the power house now claim that one of their most disagreeable problems—soot handling—has been solved.

By soot handling, let it be understood, is not meant the cleaning of soot from the tubes, but the handling of soot after it has been cleaned from the tubes and has been deposited by gravity or otherwise in the combustion chamber. It is a problem of removal.

There are a number of very efficient and economically operating soot cleaners on the market. Whatever may be their respective methods of operation, the general results are the same—the soot removed from the tubes drops to the bottom of the combustion chamber, or it is carried on to the stack, where a certain amount is deposited in the stack base.

Removing this soot from combustion chamber or stack base is a necessary, but dirty job. If the soot is removed in the time honored way, a wheel barrow is backed up to a clean-out door and a long-handled shovel is put to work. Little need be said about the results. The soot is finally removed—but in a costly and unsatisfactory manner.

And now the steam jet method of soot handling has come to light.

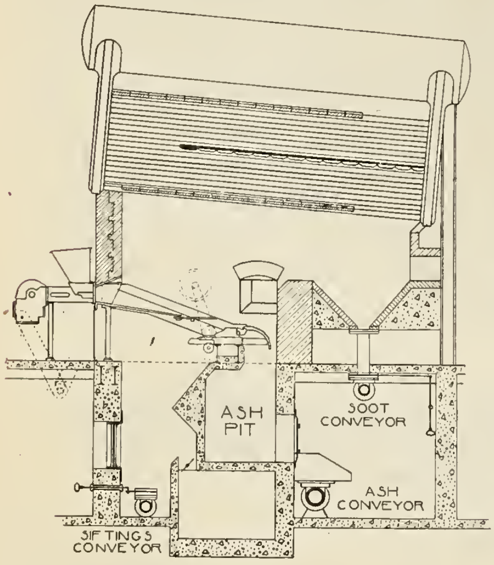

Figure 1

The steam jet method of ash handling has been employed by progressve power plants for many years. The soot handling equipment is but a logical adoption of the steam jet conveyor, indeed the design of equipment and the method of handling are similar.

A line of hard metal pipe (either 4 or 6 inches in diameter, depending on engineering conditions) is laid in a trench in the boiler room floor. Intakes are so located that the soot can easily be withdrawn through the clean-out doors and fed into the conveyor line. A jet of high pressure steam entering the system just beyond the last intake creates a vacuum in the pipe line, which, in turn, creates a suction. The current of air carries the soot to the jet, from which point the soot is ejected through the discharge line to the tank or receiving receptacle. Like the tanks used for receiving ashes, those of section cast iron design are to be preferred. They should be equipped with water sprays or wash vents to clean the steam of all dust as it emerges.

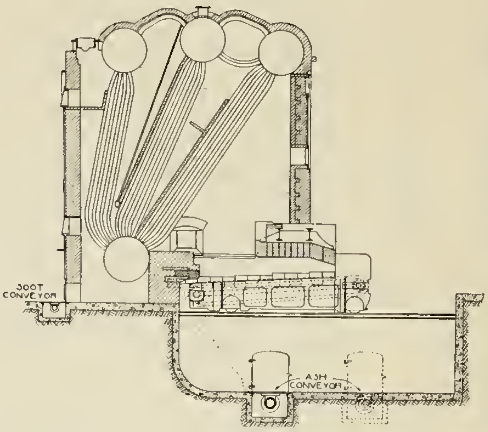

Figure 5

Figure 1 shows a soot conveyor located in the rear of a water-tube boiler, over a chain grate stoker. An ash conveyor with optional location is indicated in the diagram. In this installation, the soot is hoed or raked through the clean-out door and fed into the conveyor intake. No shovelling or wheeling is necessary.

Another type of installation is indicated in Figure II. Here we have the soot conveyor located under a soot hopper; the flow of materials from the combustion chamber to the conveyor being controlled by the operation of a slide.

In operating this installation, the steam valve is opened and the slide removed. The soot feeds automatically into the conveyor, and when the accumulation is removed, the slide is closed and the steam valve closed.

Peek holes or inspection doors are not necessary, as the operation of the conveyor may be determined by sound. When the conveyor line is running empty, a loud, harsh roaring is heard. As the soot is fed into it, the sound is deadened into a low, muffled rumble.

This type of soot conveyor can easily be applied to stack bases and economisers. Coal siftings, too fine for the grates, can also be handled by means of a steam jet conveyor.

It must not be supposed that conveyors of this type are in a preliminary stage. They are in actual use and are satisfactorily doing their work.

Chief engineers who are interested in removal of soot by the steam jet method can receive information from Mr. R. E. Cleaton, of the Cleaton Company (Canada) Ltd., Montreal, who are Canadian representatives and engineers for the Conveyors Corporation of America, the manufacturer of this type of equipment.

PREVENTS BUTTON LOSS

An improvement recently made in the button which hold the chart on recording thermometers and gauges will be welcomed by users of these instruments. Not only does the latest innovation do away with the trouble of unscrewing and removing the button and then replacing it every time a new chart is to be put on the instrument, but it eliminates all possibility of losing the button.

On the recorders now being placed on the market by the Schaeffer & Budenberg Mfg. Co., and the American Steam Gauge and Valve Co., there is a patented chart holder which cannot be removed.

A simple quarter turn draws in the little metal clips, or fingers, and permits chart to be removed. Another slight turn in the opposite direction pushes out the clips again and they grip the new chart firmly.

Announcements

Engineering and Machine Works, St. Catharines, have been awarded the contract for two 54 x 14 horizontal return tubular boilers for the new Coca-Cola building, Toronto.

Arthur S. Leitch Co., Toronto, heating and ventilating engineers, report the following contracts recently placed: For Jarvis Collegiate Institute, Toronto c Nash, size C, Jennings hytor-vacuum duplex pump 52,000 feet direct radiating capacity, also a type C single pump of 26,000 feet capacity. For Silverthorn School, a Nash C-type pump; Galt Collegiate, a duplex C-type; Reg. N. Boxer Co., Toronto, a single C-type; Phoenix Ave. School, duplex B-type, 32,000 feet capacity; Wyandotte School, Windsor, M-type, 500 square feet; Robert Reford Building, Toronto, A-type, 8,000 square feet; Coca-Cola Bldg., Toronto, C-type, duplex; Dovercourt Road church, A-type. Western University, London, C-type, duplex. Sims heaters are being installed in Jarvis Collegiate,

Test this sheet packing

—try it where others have failed

Pick the meanest sheet packing condition in your plant and try Service Sheet on it—that's the engineering way to prove facts.

Thousands of engineers have tested Service Sheet on almost everything from mercury vapor to molasses—and with this result:

—that Service Sheet will stand up under more conditions, and stand up better, than any other sheet packing on the market.

Service Sheet meets practically every sheet packing need of the average plant. It replaces numerous "special" styles, simplifying your packing stock, reducing the investment, preventing mistakes, and eliminating deterioration.

Service Sheet is so dense and resilient that it can be used half as thick as other packings—a direct saving of material.

And remember, Service Sheet is absolutely reliable as well as economical.

Toronto; Toronto Transportation Co.'s building, Coca-Cola building, and a Sims garbage burner in Hotel Dieu, Windsor, while the Canadian Salt Co., Windsor are installing a No. 3 Nash hytor chlorine compressor.

Irving Iron Works Co. of Long Island City, N. Y., who some time ago established a sales branch in Montreal with L. Gomes in charge, have changed their address from No. 64 Decelles Street to 304 Coristine Building, Montreal.

The Canadian Clothel Refrigeration Co., have temporarily closed their Montreal offices and, until further arrangement has been made, are being represented by A. G. Kidston & Co., 17 St. John Street.

Annual Banquet of the Quebec branch of the Canadian Manufacturers' Association will be held in the Windsor Hotel, Montreal, on May 15. Sir Auckland Geddes, British Ambassador to Washington, will be extended an invitation as guest of honor.

The Voorhees Rubber Company of Jersey City, N. J., who are well known to Canadian jobbers as manufacturers of belting and hose, have recently established a Canadian branch. The Canadian company will be known as The Voorhees Rubber Manufacturing Company of Canada. Head Office, 10 Victoria Street, Montreal. This office will be under the management of E. R. Fenwick.

The Devoe Electric Switch Company, of Montreal and Toronto, have just been awarded the contract for the panels and switch boards for the new T. Eaton Company store in Toronto.

Lighting safety panels will be installed throughout. These panels are built on one solid base of "bakelite." This contract was awarded because of the general rugged construction of this style of panel and will amount to upwards of $15,000 exclusive of installation costs.

This is the firm who supplied all panels and switch boards installed in the King Edward Annex, the Royal Bank Building and the Union Station, all three of Toronto as well as the Mount Royal Hotel in the City of Montreal.

E. A. Barnes, of the Semet-Solvay Co. has made some interesting announcements regarding the new plant that his company is constructing in Hamilton for the Hamilton By-Products Coke Ovens Company. The complete project will cost $2,500,000; the approximate cost of the buildings and equipment, $2,000,000 and at least 90 per cent. of this amount, or roughly speaking, $1,800,000, will be spent in Canada. Contracts for electrical equipment have not yet been awarded. The new plant will be in operation by November this year. The plant will also have a minimum capacity of 5,000,000 cubic feet of gas per day, and a maximum of 7,000,000. In addition, the company will manufacture from 300 tons to 350 tons of coke per day.

Monday, April 30, marked the removal of the Toronto Branch of Crane, Ltd., to their new establishment at 306 Front St., W., recently completed for them by Anglin Norcross, Ltd. The new building is one of the best examples of modern construction in Toronto, being fireproof throughout and embodying in its design, the results of years of experience in the particular work required.

A feature of the new building, which combines, the offices, showrooms, and warehouse, is the attention which has been given to lighting, and to the comfort of the employees. Among the exceptional features are, a shower bath for the male employees and a completely equipped rest room for the office staff. It is planned to add a cafeteria to the plant at an early date.

During the time of the removal from the old location at 526 Bay St., not a delivery was missed by the company, due largely to the provision made by the installation of a special siding at the rear of the new warehouse.

Construction

St. Vincent de Paul Hospital, Sherbrooke, contemplate a $600,000 addition. J. W. Gregoire, 16 Wellington Street South, Sherbrooke, is the architect.

Toronto Board of Control voted $5,000,000 last week to the Toronto Transportation Commission for its program of rehabilitation and construction.

Belleville City Council have passed a by-law for a $15,000 improvement to the civic gas plant. A new gasification system will be installed with the object of lowering the cost of production.

Kilgour Bros., 21 Wellington Street West, Toronto, will shortly call for tenders for the erection of a factory costing about $100,000. D. C. Cotton, 54 Adelaide Street West, is the architect.

Bank of Montreal will build a new structure on King Street, Kingston, to cost about $125,000. A. Terenent, superintendent of the John V. Gray Construction Co., Toronto, general contractors, will handle the work.

Brown Corporation, La Tuque, Que., contemplate the erection of a paper mill at St. Angele de Laval. Geo. Boswell, 19 St. Genevieve Street, Quebec, is the manager of the company. The mill when completed will cost about $5,000,000.

Canada Life Assurance Co. will shortly erect a $300,000 office building on the south-east corner of Gerrard and Yonge Streets, Toronto. The new building will be three storeys in height and will be built where the Forum Building now stands.

Yolles & Rottenberg, Ltd., 366 Adelaide Street West, Toronto, are having plans prepared for the erection of a ten-storey textile manufacturing building at the corner of York and Front Streets, at an estimated cost of $1,000,000.

Dominion Iron & Steel Co., North Sydney, N. S., will shortly instal an electrically operated belt conveyor, 75 feet long and return, also an endless haulage wire for handling coal cars on piers.

Building Committee of the Toronto Board of Education has called for tenders for the work of adding eight class-rooms to the Riverdale Collegiate, to cost $120,000; a six-room addition to the Ogden Street school, to cost $53,000, and a six-room addition to the Lansdowne school.

Robert Simpson Co., Toronto, will commence construction work on the addition to their store, which will cost about $1,000,000, the middle of next week. There will be an entrance on Queen Street opposite the City Hall, also one on Richmond Street, which will lead direct to the basement.

Construction work on the new St. Andrews College at York Mills, Ont., will commence this fall. The new group of buildings, when completed, will be among the finest in Canada, and will cost about $400,000. The site comprises about 135 acres. Sproatt and Rolph are the architects.

Linde Canadian Refrigeration Co., Vancouver, have received contracts for the erection of a pre-cooling plant for the United Growers' Association of Chilliwack, B. C., costing $13,000, and for a similar plant to be erected for the Maple Ridge Growers Association at Port Haney, B. C., costing the same amount.

Memorial Hall will be built in Montreal by the Imperial Order of Daughters of the Empire, of that city. The total cost of the structure is estimated at $500,000. The new hall will have a seating capacity of 4,000. A suitable site has been offered by the McGill University. Headquarters of the Order are located in the Ogilvy Building, Montreal.

Plans for the erection of a pulp and paper mill in North Vancouver, at a cost of $8,000,000, are nearing completion in the offices of the Seamon Paper Co., Chicago. The company is already interested in the British Columbia paper industry, as its president for years was a director of the Whalen Pulp & Paper Co. 50,000 h.p. will be used in the mill when completed. The mill will employ about 1,000 hands, and will have a capacity of 250 tons per day.

Contracts have been awarded for the erection of the new Ottawa Auditorium on O'Connor Street. General contract has been let to T. C. James, Ottawa, and structural steel contract to Dominion Bridge Co., Lachine, Que. Work will be started and it is expected the structure will be completed by November 1. The building is to cost about $335,000. Contract for the ice-making plant has not yet been awarded. Tenders for this are now being received, and Major R. Percy Sims, Montreal, will suggest to the Board of Directors, which tender should be accepted. Richards & Abra, Ottawa, are the architects.

Heavy Pumping Equipment

This Single Acting Triplex Power Pump is used to a large extent in supplying boiler feed in mines, paper mills, and elsewhere. It is a strong, well built pump for working pressures up to 150 pounds per square inch.

Steel crank shafts, fine cut gears and deep stuffing boxes make this one one of Smart-Turner's dependable pumps — sturdily strong.

Foot Valves and Strainers.
Steel Barrels.

WHY FLUE GAS ANALYSIS TALKS FURNACE EFFICIENCY

(Continued from page 31)

when and how, the losses occur and will suggest the remedies that may be applied if we have parallel lines of information upon the draft, the fuel bed thickness in the case of coal, and the uptake temperature. You do not guess at the height of the water in the boiler or at the steam pressure, so why should you guess at the draft and the analysis of the flue gases?

Early Methods

When the importance and dividend-paying value of analyzing waste gases from boiler furnaces, internal combustion engines, kilns, etc., (as well as the valuable gases from gas producers, gas benches, water gas sets, bee-hive ovens, by-product coke ovens and the like), had become established, operating engineers and consultants looked for the best means of making accurate analyses rapidly. Orsat, a French chemist, devised a laboratory instrument for making volumetric analyses a good many years ago and his method having been found to be the correct one, numerous styles of "Orsat" gas analyzers were offered for sale. These instruments were constructed almost entirely of hand-blown glass parts and owing to their fragility, cumbersomeness and other undesirable features, were not well suited to engineering work. What is needed is a compact, rugged, portable, "fast," accurate analyzer which can be handled by ordinary workmen.

Principle of Gas Analysis

If you wished to know how much chaff, by volume, there might be in a bushel of wheat you would first carefully measure out an exact bushel by volume of the mixed chaff and wheat. You would probably take a bushel measure, fill it heaping full and run a straight edge across the top of it. You would remove the chaff and carefully measure the wheat; the shrinkage would be the volume of the chaff. The steps you take in making a gas analysis with an Orsat type analyzer are analogous, but you cannot handle gas as you would handle wheat or any solid substance. Gases have the property of elasticity, and unless you confine them they will get away from you. Moreover, the volume of any gas is affected by pressure and by temperature, and we must have means of controlling both within the limits of accuracy required by the work.

A mixture of gases is analyzed by the "Volumetric Method"—that is, a measured volume of the mixture is taken and one of the gases is removed by absorption. The volume remaining is then measured and the shrinkage indicates the percentage of the gas absorbed. The residue volume is then exposed to another absorber which removes another gas. On re-measuring, the volume of that gas becomes known, and so on until all of the gases have been determined. The "volumetric method" is employed because it is exceeding difficult to weigh gases. If the weights are desired these can be easily computed when the percentages by volume are known.

Apparatus Employed

The illustration shows a standard three-chamber gas analyzer used to test for carbon dioxide (CO_2), oxygen (O_2) and carbon monoxide (CO). This instrument is marked by several features worthy of particular mention.

Special metal valves are used instead of frail glass stop cocks or troublesome pinch clamps on rubber connections. The advantage is obvious to any practical engineer but best known by those who have had a glass cock break or stick at the time of an important test, or who have had a rubber connection "set," or show a leak while being carried in a suit case. The metal valves with their renewable seats and packing nut connections are easy to manipulate; they are far from fragile, and when closed after a test they allow the analyzer to be carried in any position. The stems and seats are constructed of non-corrosive metals and so are not affected by the absorbed chemicals or the gases.

The use of fibrous material in the absorption chambers serves the dual purpose of breaking up the gas sample and presenting a very large exposed, wet surface for absorption.

Pounding Plibrico into place to form a front door arch.

What is PLIBRICO? JOINTLESS

FURNACE LINING

PLIBRICO is a plastic furnace lining in unbaked form that meets all furnace requirements and that can be installed by anyone who can use a mallet and trowel. When baked, it forms a one-piece, jointless furnace lining that is resistant to temperatures to 3100 degrees F. Plibrico outlasts ordinary fire brick two to four times. It eliminates the joints—the root of all furnace trouble—and so gives a lining that will not crack, spall off or bag.

Plibrico is stocked in warehouses for immediate delivery in 52 principal cities throughout the United States and Canada. **It is delivered only in steel containers of distinctive appearance as shown below.** This container keeps Plibrico fresh and plastic and identifies the original.

Steam Jet Conveyor Economy

Discharge of Modern Type of Equipment No Longer Productive of Excessive Dust

*BY GUY S. HAMILTON

THE power plant engineer who is about to purchase ash handling equipment for his plant has before him a wide variety of conveyors from which to choose.

Where more than one method of ash handling is under consideration, logic compels the adoption of that type which combines in itself the greatest number of advantages for the conditions for which it is required.

The usual argument against the use of the steam jet conveyor is that it requires a large number of boiler horse power when in operation. This is true, comparatively speaking, when considered in comparison with a 5, 10 or 15 H. P. motor. But the action of this type of conveyor being extremely rapid, with great capacity, necessitating usage for only a very short period of time, this apparently large consumption of power becomes nominal and low it is claimed by the manufacturer.

Laud Soot Blowers

Most engineers are thoroughly familiar with soot blowers and will almost invariably be found to be enthusiastic advocates of their installation. They never regard them as a drain on their boilers nor do they make accusations of extravagance in their use of steam, but the rate of flow of steam for the soot blower per minute is no less at any time than for the steam jet conveyor and in some instances may be found to be more.

The steam soot blower is an accepted piece of equipment. It has found its place and by sheer merit has held it. Engineers regard it favorably because they know what it will do, but not being familiar with ash conveyors they hastily jump to conclusions.

Refute Objections

Two other arguments are frequently advanced against the use of steam jet ash conveyors:

It will pack ashes in a bin or tank where it is necessary to store for a period of time.

The discharge of the conveyor is productive of a great deal of dust.

These arguments were true in earlier types of steam jet ash conveyors but they no longer are true to-day with modern designed equipment.

Another important feature claimed for the steam jet ash conveyor lies in the fact that it can be operated by labor devoid of any mechanical ability.

Interruptions Costly

Interruptions of service, what are usually considered solely from the inconvenience and annoyance involved should and can be translated into a tangible value of dollars and cents.

The steam jet conveyor from its simplicity of construction does not require an extensive supply of repair parts, consequently a very small amount of money is tied up in parts.

With the steam conveyor, in the event that a repair part should not be on hand, an emergency repair can be made which will tide over until a part can be procured from the factory.

---

In changing the speed of a Corliss engine the governor should be pulleyed so that it will run at the speed for which it was intended. A little departure from this speed will keep it against one or the other of its stops.

* * *

Cement of value in filling up small leaks such as blow holes in a casting is composed of 5 lb. paris white, 5 lb. yellow ochre, 10 lb. litharge, 5 lb. red lead, and 4 lb. black oxide manganese. Mix these materials thoroughly and add a small quantity of asbestos and boiled oil This cement will set hard in from two to five hours and will not be subject to expansion and contraction to an extent sufficient to cause leakage afterwards.

Construction

(Continued from page 42)

British Empire Steel Corporation are spending $30,000 on an enlargement to the electric plant at New Waterford, N. S.

Canadian Atlas Crucible Steel Co., Welland, Ont., are in the market for a 500 h.p., 750 r.p.m., 4,400 volts, 25 cycle, 3 phase, wound rotor or slip ring, 40 deg. rating motor.

J. & J. Cash, Inc., of South Norwalk, Conn., and of Coventry, England, will establish a branch plant at Belleville. The company conducts an extensive textile industry.

Bridge River Power Co., Seton, B. C., are having plans prepared for a $12,000,000 power development, including gravity dam, power house and transmission lines. H. Holgate is the engineer.

Y. W. C. A., Toronto, will rebuild their headquarters on McGill Street. A campaign has been launched with an objective of $350,000. Construction work is expected to start some time this summer.

Hawkesbury Industrial Corporation, Hawkesbury, Ont., have been incorporated to build and operate electric plants, industrial plants, etc., with a capital of $100,000.

Residents of Hamilton Mountain have applied to the city for additional water supply. Equipment necessary will be pumps of larger capacity, replacing the two one-million gallon centrifugal pumps now in operation. The estimated increase in cost is $15,000.

Toronto, Ont.—The Toronto Hydro-Electric System, Yonge and Shuter Sts., will construct extensions and improvements to its lighting and power system, including poles, transformers, conduit, wire, cable, switches, etc. Estimated cost $2,000,000.

* * *

E. Gordon has been appointed sales manager for the Bull-Dog Belt Lacer Co., 85 Cannon Street West, Hamilton. Mr. Thompson, also connected with the above concern, states that they are very busy at present, and enquiries are coming in from quite a scattered territory, ranging from the Maritime provinces to British Columbia.

CLASSIFIED ADVERTISEMENTS

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads set in border, are at the card rates.

Every Engineer, Mechanic and Electrical Worker will welcome this new master set. It will answer your problems.

It will help you with your daily work.—A sure source of advancement and higher pay. Complete up-to-date information that is thoroughly and easily explained on every branch of modern engineering and electrical practice.

AUDEL'S ENGINEERS & MECHANICS GUIDES

4750 PAGES — $1 A MONTH
8754 ILLUSTRATIONS — $12 COMPLETE

These Guides tell you all about—

Theory, Practice and Operation of ALL Steam Engines; UNIFLOW and POPPET VALVE ENGINES, and LOCOMOBILES. Locomotive-Marine Engines; Turbines; Rotary Engines --the Indicator--Lubrication--PRACTICAL MANAGEMENT. GAS, GAS ENGINES--*Aeroplanes* and *Aviation*--HOW TO SELECT AN ENGINE. STEAM ENGINE rules and formulae. Steam Boilers; Heat-Combustion; Fuel and Flue Gas Analysis-C02 Recorders-Construction of all types of Boilers.--Mechanical Stockers--Oil Burners--Setting--Chimneys--Mechanical Draught --HOW TO SELECT A BOILER--BOILER DESIGN based on A S.M.E. BOILER CODE--OPERATION FIRING. Pipes, Fittings--Heating and Ventilation--Refrigeration--Cooling Towers --Condensers--Distilling Apparatus--Elevators--Cranes--Ropes and Cables--Splicing--*Practical Electrical Engineering* as an aid for engineers and electricians in obtaining a license--ready reference Index, covering entire field of Modern Electricity.

SHIPPED TO YOU FREE

Not a cent to pay until you see the books. No obligation to pay unless you are satisfied. Send coupon now--today and get this new master set for engineers. Pay only $1 a month.

POSITION WANTED

FACTORY SUPERINTENDENT OR CHIEF Engineer is open for engagement. Have had wide experience in operating power plants and handling help in Canada. Apply Box 107, Power House.

FOR SALE

BOILERS FOR SALE CHEAP—TWO 100 horsepower, 110 pound steam. Apply Box 102 Power House.

BURNHAM STEAM PRESSURE PUMP, 10 IN. x 1¼-inch. x 12 in., nearly new, with Fisher governor attached. W. Ahearn, 538 McLaren St., Ottawa. When answering this advertisement please mention this paper. P.F.H.

FOR SALE—ONE 10 H.P. STEAM BOILER with base and 20 ft. smokestack; new flues and in A1 condition; also 1 steam turbine bottle washer and sterilizer; both in excellent working order. Apply Box, 103 Power House.

INDUCTION MOTOR — 220 VOLTS — 1800 r.p.m. 15 h.p.; single phase; can be bought cheap; write for particulars. Box 104, Power House.

I. H.C. 12 H.P. GAS ENGINE FOR SALE—ALL in good running shape, with 33-inch clutch pulley; will be sold reasonable on easy terms. Apply W. Harrison & Son, R. R. No. 5, Guelph. When answering this advertisement, please mention this paper. P.F.H.

SAWMILL MACHINERY—MODERN DESIGN—most satisfactory to operate. Apply Box 105, Power House.

SAWMILLS—PORTABLE — DOUBLE EDGES; also all kinds sawmill machinery. Apply Box 106, Power House.

TAYLOR SAFES FOR SALE—RARE OPPORTUNITY to secure a safe at small cost. They are in splendid condition. Inside dimensions and prices are as follows: 15" deep, 2 ft. 6" wide, 3 ft. 11½" high, fitted with built-in compartment. Price $250.00. 18" deep, 2 ft. 8" wide, 4 ft. 5" high, fitted with steel compartment. Price $200.00. Apply Box 10, POWER HOUSE.

WELDING

ELECTRIC AND ACETYLENE WELDING of broken castings and machine parts, boilers, tanks, and marine repairs. Carter Welding Co., Ltd., 165 Adelaide West, Toronto. Adelaide 2841.

BELTING BARGAIN

ABSOLUTE BELTING BARGAINS—BELTING every description; rubber hose, thresher supplies, tank pumps, pump leather feeds, canvas, McGill auto powers, special reduced prices; for quality and price, you can't beat us. N. Smith, 134 Adelaide west, corner of York, Toronto. When answering this advertisement, please mention this paper. P.F.H.

REFINITE
RIVAL OF THE CLOUDS
TRADE MARK

Nature's Water Softener
Copyright 1920—The Refinite Co.

For Boiler Feed Water

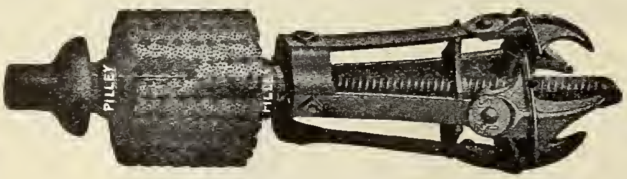
Refinite makes scale impossible. It takes out the scale-forming lime and magnesia before the water enters the boilers. You save not only fuel, but the trouble, time and expense of washing boilers and replacing tubes.

A coating of scale even 1-50 in. thickness wastes 100 lbs. from every ton of coal fired.

Write for Information and Catalogue.

Refinite Company of Canada, Limited
305 Continental Life Building, Toronto

The Simplest and best cleaner on the market is



PILLEY'S

Combination Flue Brush and Scraper.
Guaranteed not to break or the wires to pull out or lay over
A simple turn of the hand adjusts it to the tube, and the brush removes what the scraper loosens.

Tycos and Superheat

A *Tycos* Superheated Thermometer installed on both ends of the superheated steam line will indicate the temperature performances and losses due to pipe radiation.

A *Tycos* Bi-Record Recording Thermometer at the power unit gives accurate records of both temperature and pressure of the superheated steam as it is delivered. These records are made on one chart simultaneously. These charts are invaluable in determining the costs of producing superheated steam and for determining power plant efficiency.

SONDERGLASS

"The Unbreakable Boiler Gauge Glass"

Two Glass Tubes in One

The different metals used allow for expansion and changes of temperature to which the glass is subjected, and add greatly to its pressure-resisting qualities, as each of these metals has different degrees of expansion. The inside of the tube expands in proportion to the temperature of the steam or hot water and the outside according to the temperature of the air.

Special Offer

48 Issues (two years) $3.00

CURTIS ENGINEERING SPECIALTIES

Comprise a line of devices that have stood the test of years for the utmost in efficiency. They are built for dependable and enduring service. Scrupulous care in the selection of material and in construction, with adherence to the highest engineering standards, have won them a commanding position. The

CURTIS WATER-PRESSURE REGULATOR

will deliver water into service pipes at any desired pressure, regardless of any fluctuations of outside pressure.

Trouble with rust or clogging with sediment is prevented. Waste of water in domestic use by flying or spattering is avoided by the reduced pressure. This also prevents water hammer or concussion and prevents wear and tear on all packings and seats in valves and faucets, thus eliminating frequent plumbing bills. Adapted for use in pulp and paper mills, hotels, public buildings and dwelling houses. For ¾ in. to 2½ in. pipe, screwed. For 3 in. to 8 in. pipe flanged.

The Curtis Line of Steam Specialties contains many other notable devices. They are fully described in our No. 50 catalogue. Write for a copy.

"SAFETY"

Plastic Metallic Packing

Packing in Cotton Tubes.

For steam, water, air, gas, etc., is practically indestructible and may be used over and over again. It is

GUARANTEED TO LAST THREE YEARS WITHOUT RENEWAL

Packing in Bulk.

It is made of an alloy of the finest anti-friction metals, just hard enough for long service but not hard enough to damage any rod.

The metal is combined with the best lubricating material, making it practically SELF-LUBRICATING AND FRICTIONLESS.

Send for full particulars also about our "Safety" Superheat Sheet Packing.

STEEL MILL PACKING Company

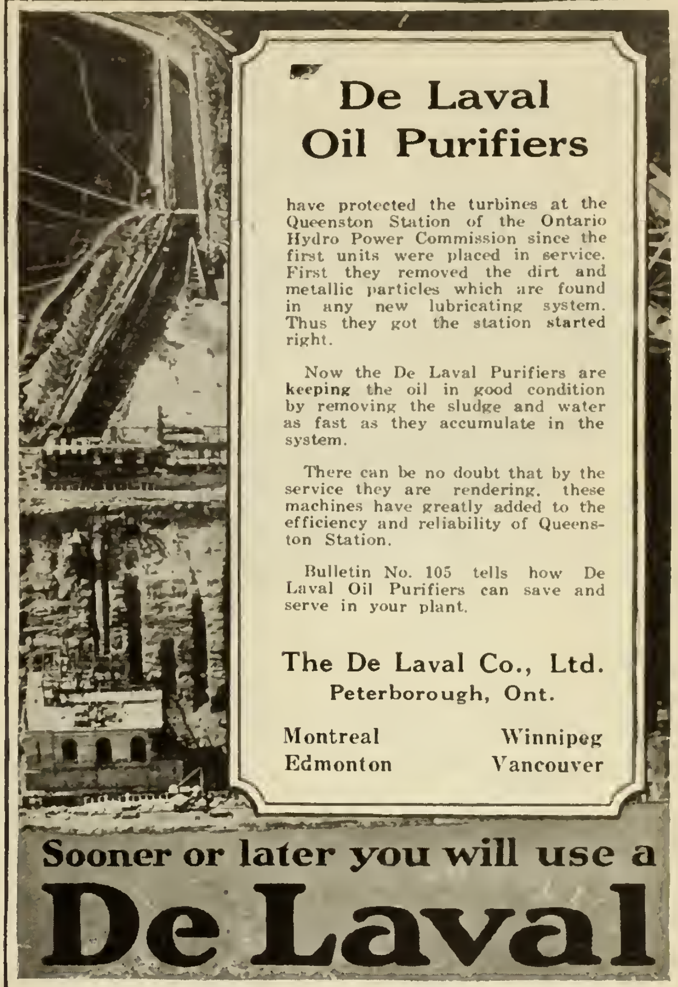
AGENTS WANTED



De Laval Oil Purifiers

have protected the turbines at the Queenston Station of the Ontario Hydro Power Commission since the first units were placed in service. First they removed the dirt and metallic particles which are found in any new lubricating system. Thus they got the station started right.

Now the De Laval Purifiers are keeping the oil in good condition by removing the sludge and water as fast as they accumulate in the system.

There can be no doubt that by the service they are rendering, these machines have greatly added to the efficiency and reliability of Queenston Station.

Bulletin No. 105 tells how De Laval Oil Purifiers can save and serve in your plant.

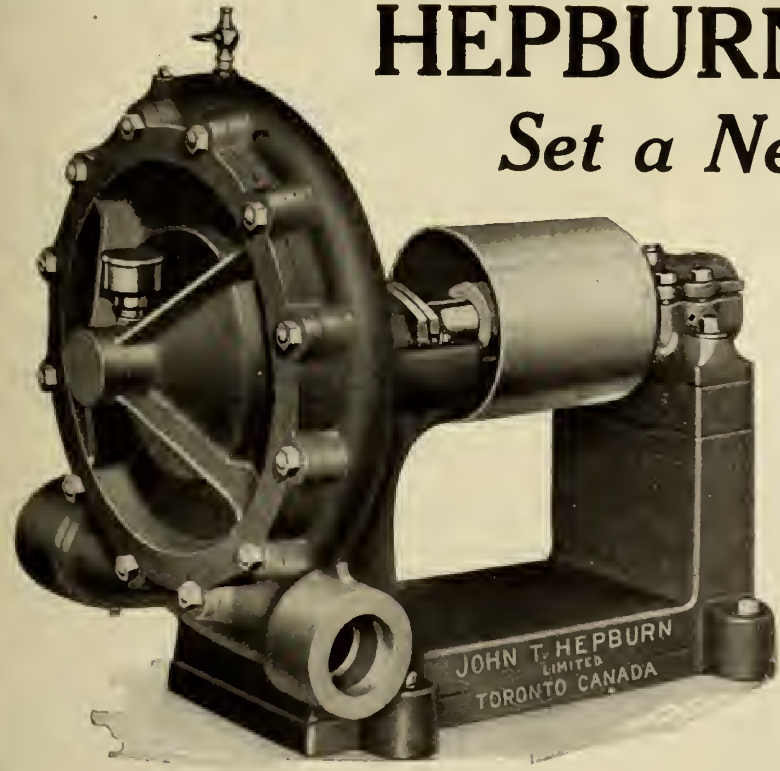
HEPBURN CANADIAN MADE **PUMPS**

Set a New Standard



The Hepburn Centrifugal Pump is not one of those "Old Stagers" which was designed 20 years ago and is still the same. It is, on the contrary, a Pump of modern design and up-to-date in every respect.

We also make Simplex and Duplex Pumps, Hand and Electric Overhead Cranes, Vertical Engines, Castings and Forgings.

Building a one-piece furnace lining without special forms.

BETSON'S
REG. U.S. TRADE MARK PAT. OFF.
PLASTIC FIRE BRICK

Makes practicable, solid, one-piece furnace linings, including front and back arches, side walls and baffles. It costs but little to install in any make or type of boiler. It saves fuel, annoying shut-downs, costly repairs, and increases the amount of power from the fuel used.

Complete details of the many uses, methods of installing, how to order, measurement blanks, etc., are contained in a booklet of information which we will gladly send you. Tell us the individual to whom it should be addressed.

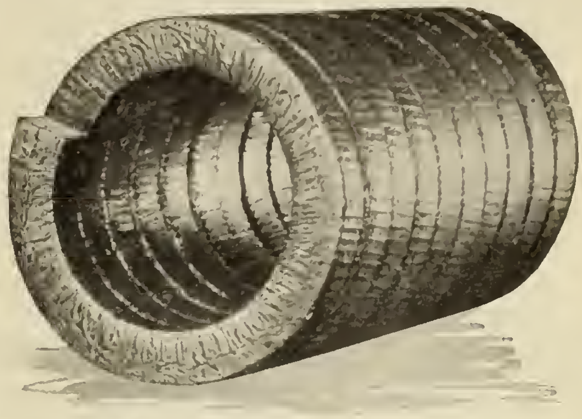
A COMPLETE SERVICE IN
"John Crane"
FLEXIBLE METALLIC PACKING



Style 100. Spirally wound Babbitt foil impregnated with purest graphite. Minimum expansion.

On Centrifugal Pumps

Positively will not score, burn or sever rods. Is non-abrasive and scales without squeezing rod, giving perfect service of extraordinary duration. This service is only one of many on rods, valves, and shafts where John Crane Style 100 is producing unexcelled results.

1923 Edition of our Text "Metallic Packing" now ready. Send for your copy.

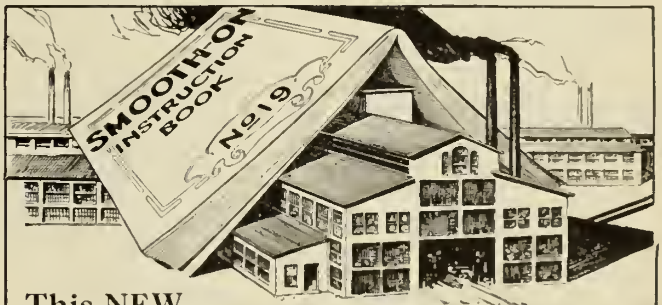
CANADIAN REPRESENTATIVES:--CANADIAN FAIRBANKS-MORSE CO., Montreal, Canada.



This NEW
Instruction Book will Cover Your Plant Repairs

From making leaky flanged and screw-thread joints tight to repairing a crack—minor repairs and some of the most serious—are illustrated and described alike in the pages of this NEW Smooth-On Instruction Book No. 19, just off the press.

Every page illustrates and describes a different power plant repair—and the descriptions are written by the engineers who did the work.

Some engineers tell how they saved hundreds of dollars through the use of Smooth-On Cements; others how they made repairs with Smooth-On which at first seemed impossible; and still others how they restored to peak load capacity, power plant parts that seemed ready for the scrap heap. Send for your copy of this NEW Edition No. 19 today—it's FREE—a postal will do.

Smooth-On Cements are sold by Supply Houses in 5-lb., 10-lb. and 25-lb. tins; also in larger sizes.

Re-Use Your Waste Oil

The amount of oil that can be collected in drip cans, properly located beneath the engine or machinery, is surprising. This oil, usually wasted, can be refined by running it through

The ANDERSON Pressure Oil Filter

and clean, usable oil, equal to the original article obtained. The operation can be repeated over and over again, cutting oil bills almost in half. It's a saving you should investigate.

Write for Catalogue.

The Longer the Experience, The Better the Babbitt

It took 37 years of progressive development to bring Magnolia Anti-Friction Metal to the supremacy which has been proven repeatedly by United States and foreign government tests. We've done all the experimenting so that the users of Magnolia Anti-Friction Metal take no chances.

To experienced power users who know good service and realize that it can be had only by taking proper precautions, Magnolia Anti-Friction Metal offers a real opportunity.

If you wish to take advantage of all possibilities in putting your power delivery and bearing maintenance costs well on the safe side, write us for performance data, etc.

Regrinding Bronze Globe Valve
for extra heavy service. Made in Sizes ¼ to 3" inclusive.

Be Free From Repair and Replacement Costs

You can bring **true** valve economy into your plant by using a "Jenkins" wherever a valve is needed.

Jenkins Valves are the least expensive because they free you from costly repair and replacement charges.

Years of experience in valve manufacturing contribute to the perfection of Jenkins design—close inspection and rigid factory tests assure the valve quality that never fails.

Jenkins Valves for every service are pictured and described in Catalog No. 9. It will be mailed you free and without obligation. Send for it to-day.

WORD PICTURES SOLVING PROBLEMS OF STATIONARY ENGINEERS

Stop that waste!

Leakage through the blow-off line causes heat waste and reduces the efficiency of the boiler.

LUNKENHEIMER Blow-off Valves

remain tight under the most extreme operating conditions because their design guards against the CAUSES of leakage by automatically cleansing the seating surfaces before the disc becomes seated and by minimizing wire drawing of the water across the seating surfaces.

Their construction permits of only a very gradual release of the water, and the danger incident to undue agitation of the water within the boiler and severe shock in the discharge line caused by sudden release, are eliminated.

Lunkenheimer Blow-off Valves embody all the requisites essential for durability, service and economy.

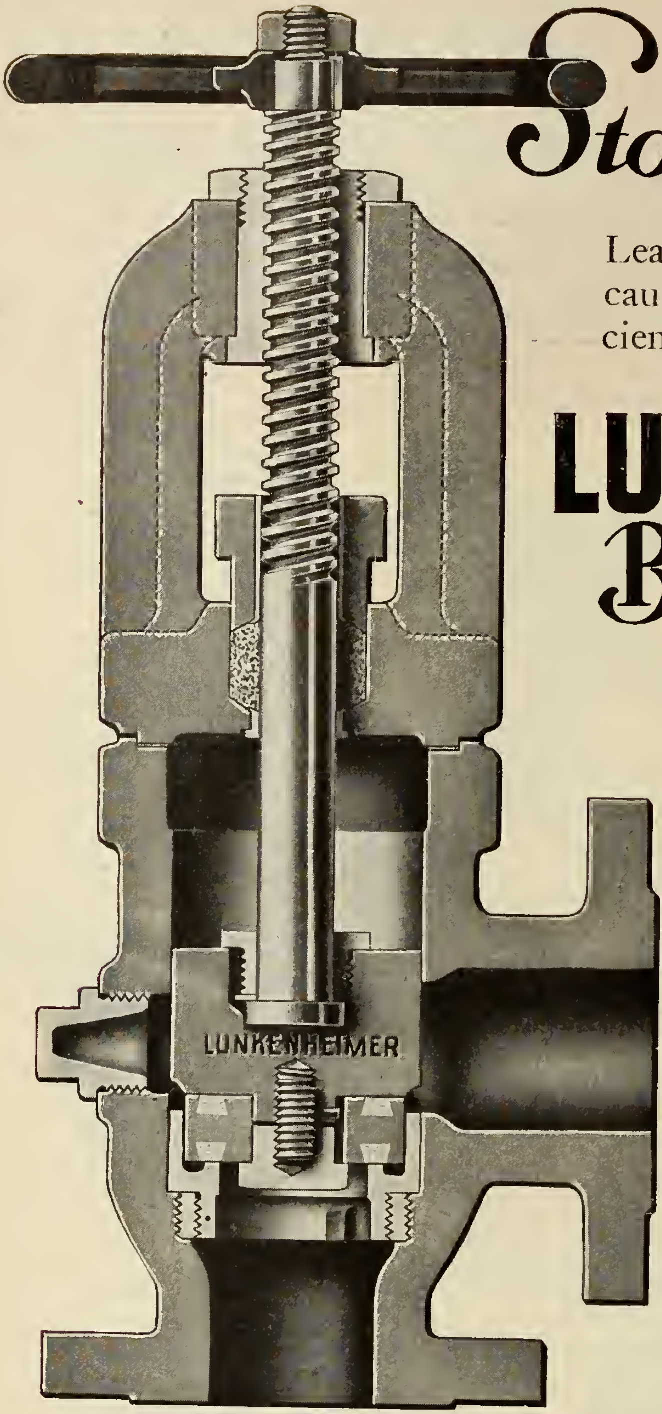

Fig. 897

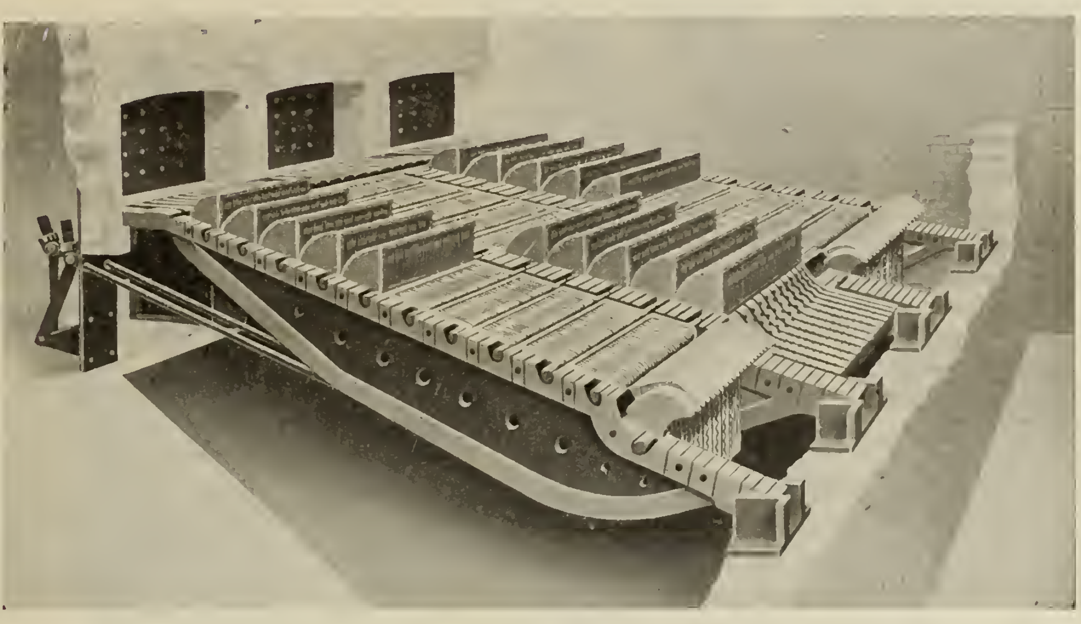
"America's Best since 1862"



THE FILES STOKER

Pays for Itself in One Year

Below is a copy of one of the many letters we have received, telling of the efficiency and economy of the Files Hand-Operated Stoker

Re FILES HAND STOKERS

Gentlemen:—

Frequently we receive letters from manufacturers, asking for information and our experience with the "Files Hand Stokers"— the most economical and efficient system of burning coal with the utmost conservation of labor.

As these inquiries are becoming more and more frequent, our better plan will be to furnish you with a letter to pass on, outlining our experience and satisfaction.

In September, 1920, we placed an order with you for two 150 H.P. Tubular Boilers, specifying our desire to have them equipped with "Files Hand Stokers." This we did on the recommendation of our United States Engineering Department, who had installed "Files Hand Stokers" in some seventeen plants, finding in them a decided saving and advantage over flat or shaking grates.

Speaking for ourselves, we have found them most satisfactory and economical, particularly so in regard to the elimination of smoke, rapid disposal of ash and clinker, thorough cleaning of fires without disturbing the active fire, and in maintaining an even bed of fuel.

We are able to keep a clean fire at all times; we have no cleaning period, for with the "Files Hand Stoker" the grate can be cleaned at peak load. It is only a matter of working one rod on each section, which can be done in less than two minutes.

The better the coal the better the result, but almost any kind of coal that will burn free can be used. With good coal, however, it is an easy matter to procure 150% boiler rating, which in reality is 12½ lbs. evaporation per pound of coal. Generally speaking, evaporation is around 7 or 8 lbs., and often as low as 5 or 6 lbs.

Our Files Hand Stokers have now been installed about two years, during which time they have paid for themselves twice over if we consider the saving in fuel.

And what we have done and are doing with them others can do.

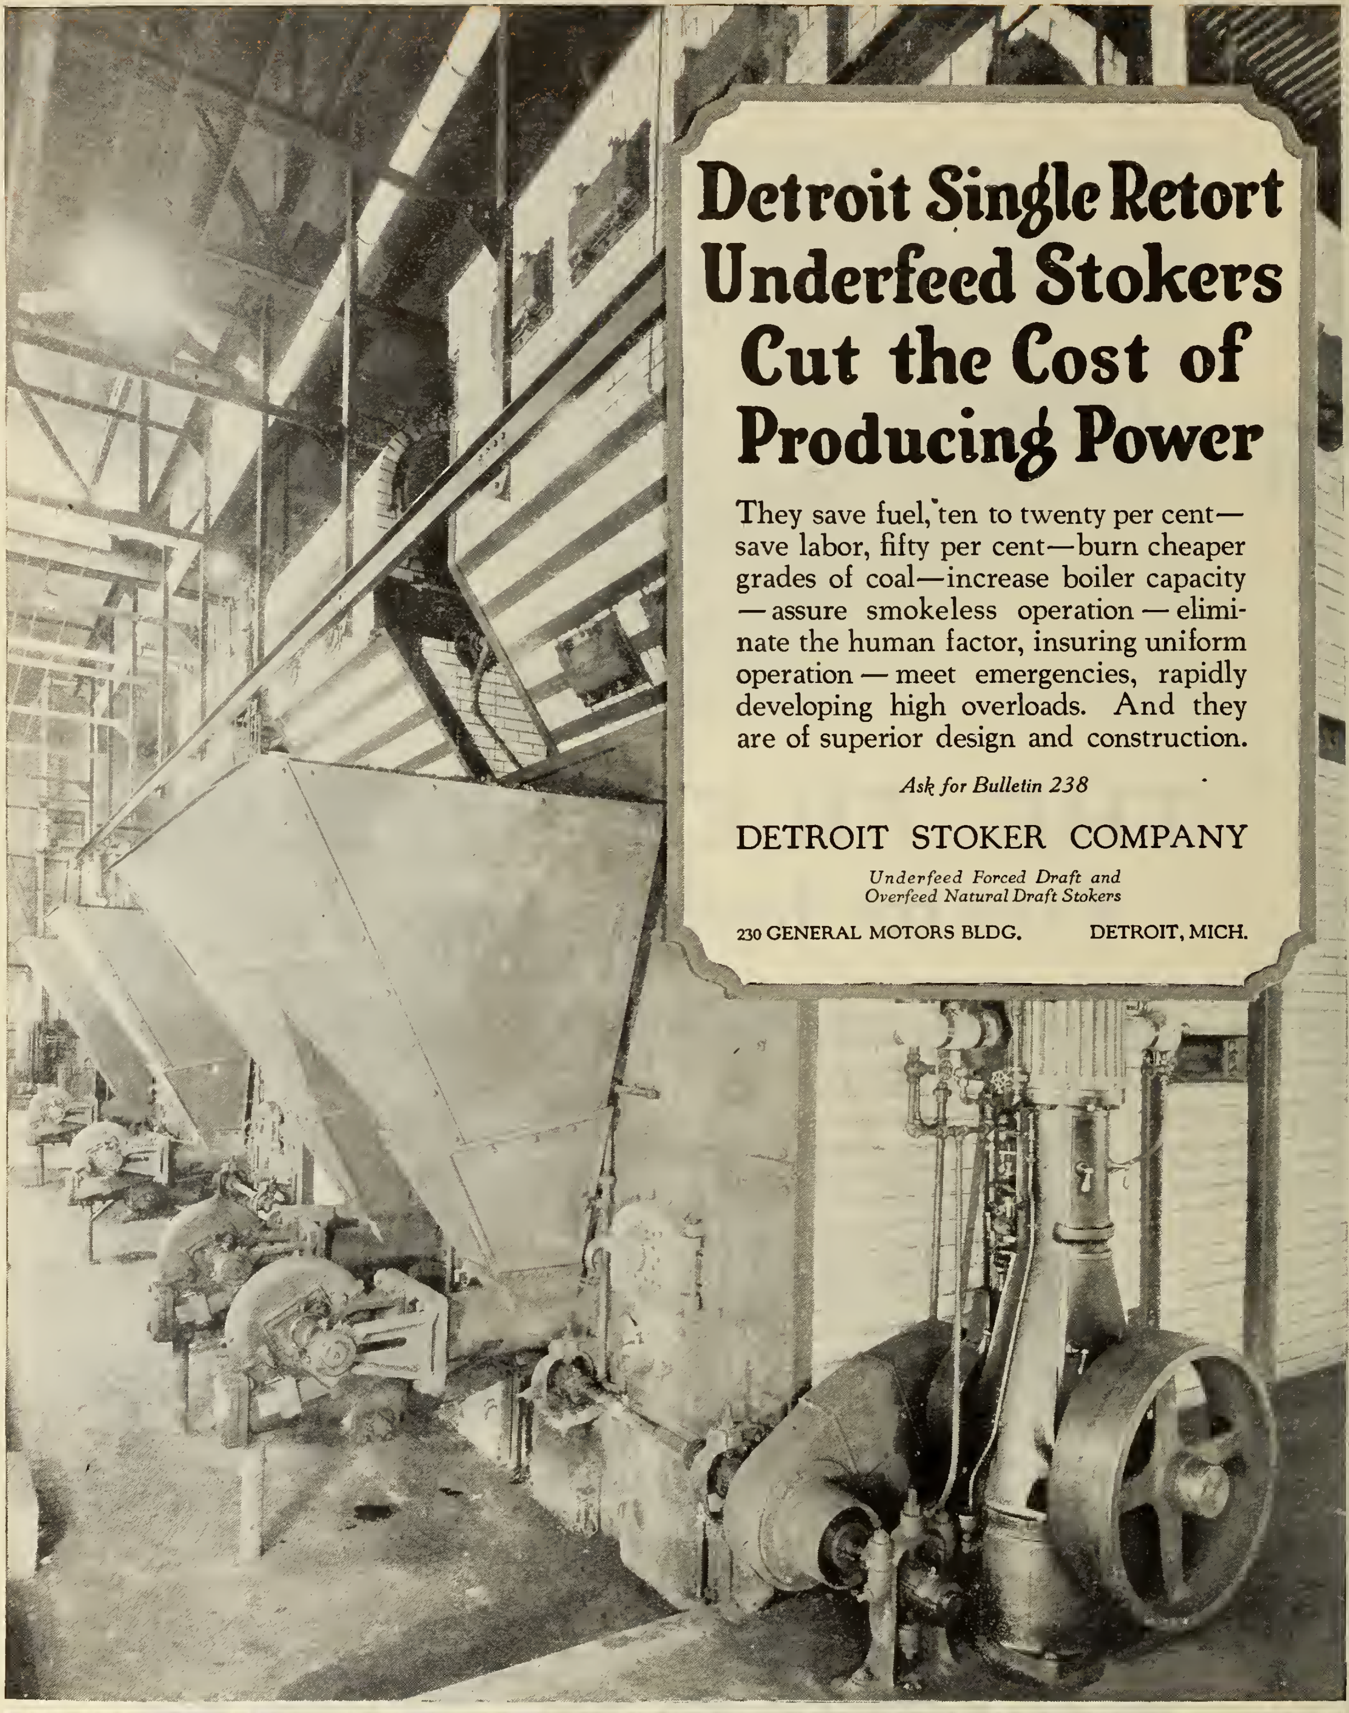
We know they effect a saving; we know they are a convenience; they have proved satisfactory in every particular, and we have no hesitation in recommending them.

Yours very truly,
THE MERIDEN BRITANNIA CO., LIMITED.

Why not Profit by others Experience?

Waterous

BRANTFORD, ONTARIO, CANADA



Detroit Single Retort Underfeed Stokers Cut the Cost of Producing Power

They save fuel, ten to twenty per cent—save labor, fifty per cent—burn cheaper grades of coal—increase boiler capacity—assure smokeless operation—eliminate the human factor, insuring uniform operation—meet emergencies, rapidly developing high overloads. And they are of superior design and construction.

STEPHEN'S
Boiler Feedwater Treatment
Insures Safe Removal of Old Scale
Prevents Formation of New Scale
It Will Not Cause Foaming
It Does Not Vaporize Away
It Stays in the Boiler
Scale Stays Out
The Old Methods Expensive, Endangering Safety of Boilers
The New Method Economical, Re-assuring Safety of Boilers

If You Want to Save Coal Bills

Save Repair Bills, Prevent Shutdowns, Lengthen Life of Boilers and Reduce Your Power Costs

Then Scale Formation. Must be Stopped.

One-eighth of an inch of scale increases coal consumption 36%. The cost of keeping scale is expensive. STEPHEN'S FEEDWATER TREATMENT is a specific cure for scale formation in boilers. It does not merely remove scale from tubes—it removes all old scale; it prevents new scale from forming and it will not cause foaming.

Stephen's engineers are men of practical experience. They can discuss your boiler feedwater problems in a practical way. Consult them freely at any time.

We don't manufacture all the feed-water treatments—BUT we manufacture the best.

Don't turn Your Factory into a Store!

Most plants that use ordinary traps are virtually compelled to "keep a store" in order to maintain a supply of extra parts sufficient to take care of repairs. For some bucket traps have as many as 43 parts that may require replacement. This not only means a lot of money tied up, but it means that you are paying someone **to make the repairs!**

The Steam Trap Sarco, on the other hand, has but five parts, and only one that moves. Consequently there is practically nothing to wear out and require replacement in the simple

STEAM TRAP SARCO

Another thing, most concerns keep a few extra traps on hand for emergencies. Here again the Sarco saves money as it costs about one-third the price of bucket traps.

The next time you have a steam trap breakdown remember **that it costs less to install a new Sarco than to repair a worn out bucket type trap.**

Hence, in most cases, you actually save money by scrapping your old trap and replacing it with a brand new Sarco.

The Sarco drains the condensate as quickly as it forms, with minimum loss of heat, instead of permitting it to collect in volume and cool off. Saves valuable heat units.

Made in sizes from ⅜ in. to 3 in., for pressures up to 200 lbs.

Write for Booklet J-32 and particulars of our 30-day Free Trial Offer.

"Always in Action"— Since 1893

How long do you think a pump governor should last and give satisfactory service?

Actually, we don't know what is the service life of Fisher Pump Governors. We do know of many that are going on doing their work, after a third of a century of duty.

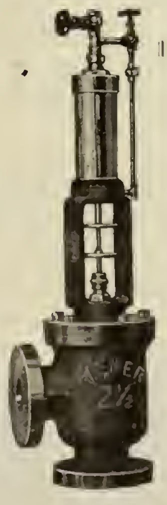
Here is an unusual instance. Read what the owners have to say;

> "The Governor we are using of your make has been in constant use on our sprinkler pump (purchased Nov. 27, 1893). This pump is always in action, *as we have no pressure tank, the pump performing that work.*
>
> Barring minor repairs, the governor *has never given us any trouble and considering its age this is a remarkable record.*"
>
> AMERICAN LINSEED OIL CO.
> St. Paul, Minn.

When you buy a Fisher specialty, you buy a lifetime of service.

Let us send you our book, "Power Plant Specialties" about Fisher Pump Governors and other power plant specialties.

The Fisher Governor Company
945 Fisher Avenue Marshalltown, Iowa, U.S.A



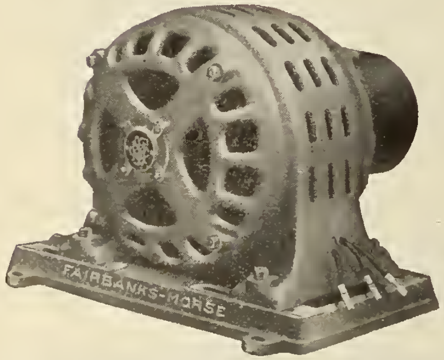
FISHER Pump Governor

(Type No. 1)

Tested, approved and listed as standard by the National Underwriters' Laboratories.

Why

Fairbanks Morse Ball Bearing MOTORS



1. They reduce friction—therefore save current.
2. They require lubrication but once a year—therefore save lubricant and maintenance charges.
3. The one-piece rotor winding means no loose joints, flashing or sparking.
4. They outlast any sleeve-type bearing motor.

A full explanation of these and other points of superiority is contained in our booklets. Prudent executives will ask our nearest branch for them.

The Seal of Satisfaction

To learn who feeds the nation, consult these figures: United States cold storage holdings April 1st, 1923, show 1,096,756,000 lbs. of frozen and cured meats, 94,920,000 lbs. frozen poultry and 37,528,000 lbs. dairy products and eggs.

"Better Refrigeration" is a subject of tremendous import as indicated by the greater study given to constructive features of cold storage houses. For instance, it has long since been demonstrated that "any old door" will not do.

Seventeen years of consistent betterment are represented in the present line of Jamison Cold Storage Doors, Windows and Ice Chutes; — *better* because they reflect the last word in insulating and refrigerating efficiency as proven in practical demonstration.

Architects, engineers, owners and superintendents are invited to write us in regard to these items. Always a full line of standard doors in stock ready for immediate shipment.

Architects and Engineers

Aside from a large stock of standard size doors ready for shipment, we build refrigerator fronts to specifications for use in any built-in refrigerator.

Send a request addressed to "Desk" please, and we will forward a catalog you ought to read.

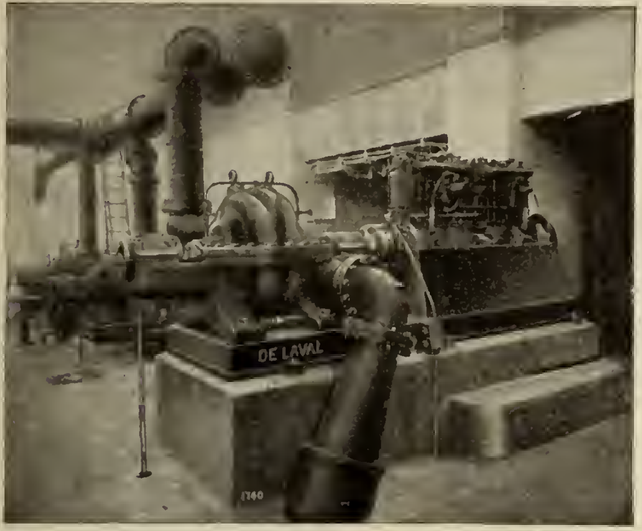
Orillia, Ont., Selects De Laval Pumps *for* Safety and Economy



THREE DE LAVAL centrifugal pumps installed in the water works pumping station of the City of Orillia, Ont., are shown herewith. The two-stage 8-in. pump in the foreground is driven by a gasoline engine, and has a capacity of 1,440 gal. per min. against 325 ft. head. The two De Laval pumps in the background are driven by electric motors. Where cheap electric power is available, this type of plant combines low cost, simplicity, and insurance against shut-down. The amount of attention required is very small, and practically no supplies are used.

The De Laval centrifugal pump is ideally adapted for both electric motor and gasoline engine drive. The starting torque is low and the power characteristic permits the size of motor to be selected to suit the normal capacity, resulting in lower power factor and higher efficiency in the driving motor. In many instances De Laval pumps are driven by self-starting synchronous motors, which can be used to correct the power factor.

State pumping requirements and ask for special publication B100

"Burn All" NONPAREIL

SHAKING AND DUMPING GRATES

A Child Can Operate It

Get *All* the Heat from *All* the Fuel

There's no sense in paying good money for fuel unless you get out of it all that's in it. To do that you've got to burn it right and you can't do that unless your Grate Bars are properly made for the job.

NONPAREIL Grates are designed and built with this one end in view. Under perfect working conditions, their 65% air space and 95% underdraft means that you can get every bit of heat out of the last bit of fuel—any grade fuel at that.

FIRE BRICK WORK You Can Depend Upon

Sexton Boiler Settings can be seen in some of the most important plants around Toronto. You can depend upon the work Sexton does, he has a reputation for doing it RIGHT and without waste of time.

Whether it's building-in boilers or just repair work of any kind, it will pay you to call in "Safety-First" Sexton. His work lasts longer, it's more efficient and it's SAFER.

Single retort simplicity —multiple retort efficiency

THE *"Lateral Retort"* construction opens the many decided advantages of multiple retort stoker firing to a large number of plants that formerly would have been compelled to install a stoker of far lower capacity and efficiency.

The *"Lateral Retort"* Stoker possesses the self-cleaning feature and the general simplicity, ease of installation, and low maintenance of the simple side dumping stoker—and adds to these advantages the fuel burning effect found in the larger and more expensive multiple retort stokers.

The construction of the *lateral retorts* is clearly shown by the illustration below. Note that from the time the fuel enters the large central retort, until it is deposited on the side dump plates as ash, it is always *underfed* insuring maximum combustion efficiency.

Isn't your plant among the hundreds that this stoker principle can benefit? The operating records of many plants now using the *"Lateral Retort"* Stoker will convince you. Write for the new bulletin—8½x11", standard filing size.

Is Canada To Become an Archipelago ?

Are we provincially insular

Do we know anything of the problems of our sister provinces

John Nelson's

"The Problems of Our Provinces"

is a series of ten articles which will appear during the next six months, commencing May 15, in MACLEAN'S MAGAZINE. John Nelson, a Canadian journalist of distinction, a publicist of authority, a writer with an unusually forceful and trenchant pen, has been assigned to visit every province and record what he discovers during his travels, without fear or favor.

Canada's Three Great Prairie Provinces

will be the subject of John Nelson's first article, and of the triumphs, the trials and tribulations of our great growing provinces, he will write. In his interesting, readable style he will give you the point of view of the farmer, the small prairie town dweller, the rich man, the poor man and his wife, the hired man. In fact no one has been overlooked in the author's careful search for facts and impressions.

There is a great big vital message for every Canadian in this fine series and every politician, every public man and every layman, his wife and his grown children should follow this series.

Other Features of the May 15th Issue Include:

"THE KICK"—Wallace Irwin.

This is a fine "long" short story by an author who has made a big reputation for himself as a regular contributor to the Saturday Evening Post.

"PUSSYFOOTING AT OTTAWA."

Grattan O'Leary in an interesting revelation of how politicians supply the public with "news." After reading this you will read between the lines of the press reports from Ottawa.

"THE BOOK"—Benge Atlee.

A fine human document by an author who has the gift of word painting. The story of a small country town doctor who holds Death at bay by strange remedies.

"THE SAND-DIVINER"—Kathlyn Rhodes.

A really startling play upon popular interest in the spirit world. Staged in Egypt, ever mysterious and ever restless, an ideal setting for the strange tale Kathlyn Rhodes has given us.

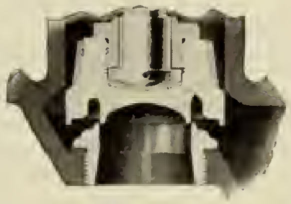
EDWARD Protected Type Seat and Disc

In the "cracked" position, the erosive action of the steam is greatest due to the fact that the steam is being wire drawn through a very small orifice and its velocity thus greatly increased. The illustrations show the positive protection which the Edward Protected Seat and Disc affords against this cutting action.

Note that in the "cracked" position the seating surfaces are widely separated and protected from the direct flow of steam and that the velocity across the seating surfaces is greatly reduced.

Send for Catalogue.



CRACKED

Unless positive means of prevention is provided, the cutting from wire drawing between the seat and disc of a valve will rapidly destroy the seating surface. This is especially true under high pressures and temperatures, where very small leaks will rapidly grow on account of the terrific erosive action, making the life of the valve very short and increasing the upkeep cost due to frequent repairs and renewals.

Storage Solves Fuel Problems of Power Plants

A Brief Outline of Precautions Essential in Handling Coal and Fuel Oils in Large Quantities With a Description of Various Types of Equipment for Economical Disposal

By ARTHUR MURPHY*

POWER plants in all parts of Canada continually face the problem of fuel supply and with each recurring shortage it is made apparent that whether coal or oil be utilized, storage in large quantities is essential; indeed the safe storage of bituminous coal is advanced by economic experts as the final solution of stabilizing the coal industry.

As long as the peaks of demand react upon the mines the coal industry must be a seasonable one but if, on the other hand, some system can be devised whereby coal can be stored economically with little deterioration or danger of spontaneous combustion the mines may be operated practically the whole year —or at least 300 days instead of 180 or 250 as at present.

Production under such operation would then be uniform with correspondingly lower costs.

Although the oil industry is more stabilized with production practically uniform throughout the whole year, the demand for the lighter fractions such as gasoline and kerosene is seasonable. During the summer months large quantities of crude oil are distilled with the result that large amounts of fuel oils are produced to meet the consumption of the winter months.

Limits Fuel Storage

In the average plant available space limits the amount of fuel it is possible to store but if economy in operation is of prime importance, sufficient storage must be provided in some way for several months' supply, although if the purpose of storage is only to insure continuity of supply much less space will be needed.

As the use of oil as a fuel is making slow headway in the larger plants of the Dominion the storage of coal is at present of greater importance and presents greater difficulties.

Large power plants in the neighborhood of cities usually have facilities for the storage of sufficient coal for their needs but plants located within a city are usually not so fortunate, space being limited and costly.

Under present day conditions only twenty per cent. of the coal recovered from the ground is actually used at the point of application. Losses in recovery, cleaning, handling, storage and methods of combustion account for this seemingly appalling loss of four tons out of every five. Experts claim that in the sub-average plant one-quarter of the coal actually fired under the boilers is wasted. Operating engineers are, however, well aware that when this condition exists there is usually some single thing which, when remedied, eliminates the bulk of this waste.

It is sometimes necessary to store coal outside a city and truck it to the plant, at best a costly procedure and one which is not improved any if when it reaches the plant the equipment necessary to place it at the boiler is obsolete in type.

There are many different types and sizes of coal handling devices on the market, but for use in handling large quantities of coal they may be generally summarized as belt conveyors, chain buckets, clam shell buckets, skip hoists and drag lines.

Offer Varying Types

Continuous conveying types vary from the endless type, used to elevate coal from under the hopper of a car, to elaborate systems with long trestles, pulleys, rollers, etc. They are used largely within power plants to convey the coal from the crushers to the coal bunkers but they also find a place in unloading cars directly into large overhead buckets.

The clam shell bucket with a locomotive type of crane, on the other hand, is used widely for unloading coal from cars and placing it in large piles. By laying a rough track as large a pile as desired may be made.

This type of equipment is also useful in reclaiming operations, especially where the coal is to be reloaded on coal cars or motor trucks.

A clamshell operated from an overhead trestle is often preferable for unloading coal from barges as well as for reclaiming the coal in the bunkers.

A cable drag scraper is useful for spreading coal in a large yard, especially when used in conjunction with a skip hoist or other form of elevating machinery. Its great advantage lies in its flexibility and simplicity. In a large yard it is only necessary to anchor posts at convenient places to which the tail blocks are fastened. The scraper spreads the coal and when reversed reclaims it to the elevating equipment.

Quickly Expose Fire

Clam shell buckets and drag scrapers are very useful if the coal pile should fire spontaneously; they will quickly dig down and expose the fire so that it can be quenched.

In comparison with the equipment necessary to handle coal, fuel oils require little equipment, a pump or pumps and a pipe line being the essentials. Pumps for fuel oil may be of several types. For large volumes and low heads centrifugal pumps are generally used; for higher heads and small quantities a gear or a reciprocating type usually finds favor.

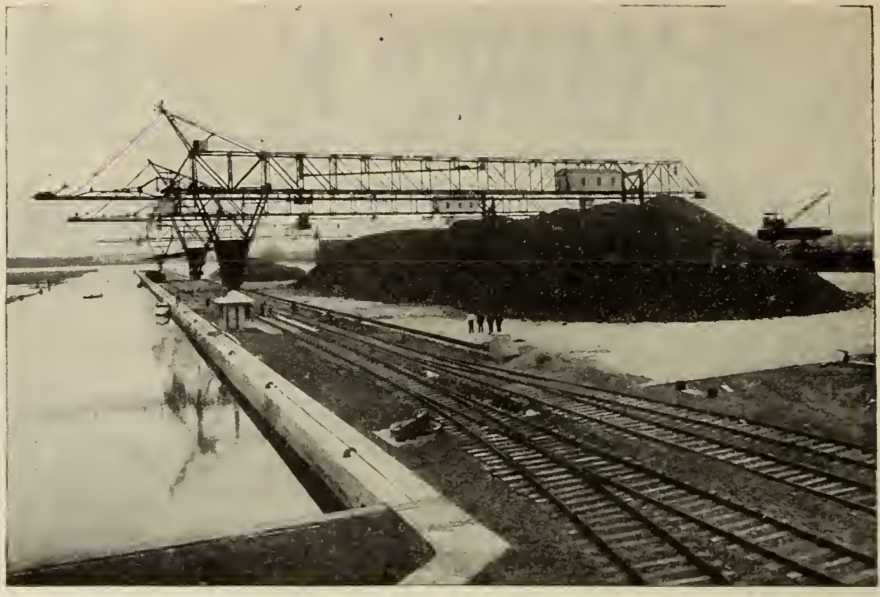
The reciprocating type, it is charged by some engineers, has one disadvantage, the difficulty of keeping the stuffing boxes tight to prevent oil dripping.

For heavy oils, in order that they may be sufficiently fluid to flow through the pump and pipe line without excessive friction losses, a steam coil is placed in the tank for heating purposes.

In storing coal the risk of spontaneous combustion is really not so great. It is extremely rare that in the smaller operations involving only a few tons there is any heating, the chief danger

---

*Associate Editor, Power House.



Traversing bridge tramway with 5½ ton grab bucket.

lying in the large piles needed as reserves for public utilities and industries.

All coals have a tendency to deterioration in storage, but the loss at ordinary temperatures is small. The tendency to fire spontaneously differs with various coals and their age, the younger coals being the more dangerous.

No case has ever been recorded in which anthracite coal has fired spontaneously, even with the finest screenings. Lignite, on the other hand, cannot be stored, even in lumps, except under water.

The degree of fineness has an important bearing on the tendency to fire, the finer the coal the greater the tendency to fire. The presence of fines in the coal pile should be avoided.

Heating a Phenomenon

The heating of coal is believed to be a surface phenomenon. If a ton of bituminous coal could be delivered in a cube, each dimension of the cube would be about 2.8 ft. When coal heats, it is due to something that goes on at the surface and not something that happens inside the piece. If the cube, having originally an area of about 47 sq. ft., be continuously divided until all the pieces are fine enough to pass through a 16 mesh screen, the area of exposed surface in one ton of coal becomes one acre.

This explains why trouble from spontaneous combustion originates in fine coal, because the great increase in area does not begin until one gets below 1½ in. or nut size. If fine coal is kept out of the pile the heating surface is so small as to remove the cause of spontaneous combustion.

Another important factor is the freshness of the broken coal surface. The freshly broken surface is much more active in uniting with oxygen than it is later, thus more heat is produced. Coal should be handled as little as possible before storing to avoid freshly broken surfaces and fine coal. For the same reason it is not advisable to crush coal before storing.

Cooling Coal Piles

Cooling a pile of coal by artificial ventilation is almost impossible on account of its low conductivity, unless the air reaches every part of the pile. A better method is the exclusion of air in order to stop oxidation, rather than attempting to dissipate the heat by artificial ventilation.

Moist air gives a lower spontaneous temperature than dry air, therefore wetting coal is not good practice unless the coal be completely immersed.

Partly oxidized coal, when mixed with fresh coal tends to inhibit spontaneous combustion; on the other hand, a mixture of two kinds of coal will heat more readily than the poorer of the two. In recent experiments with artificial mixtures of coal and pyrite in various proportions, it was found that the mixture gave a critical temperature no lower than coal alone, while pure pyrite had a critical temperature 26° C higher than the coal. Therefore, pyrite or brass lumps are not dangerous in a coal pile.

Anthracite stores best. Lignite cannot be stored except under water.

Store largest sizes possible.

Keep fines out of the pile.

Do not crush before storing.

Handle coal as little as possible.

Do not wet coal unless completely immersed.

Do not mix different kinds.

Do not ventilate coal pile.

Oils, while free from the danger of spontaneous combustion in storage are not wholly free from hazard. Tanks must be constructed and placed in compliance with underwriters and municipal regulations.

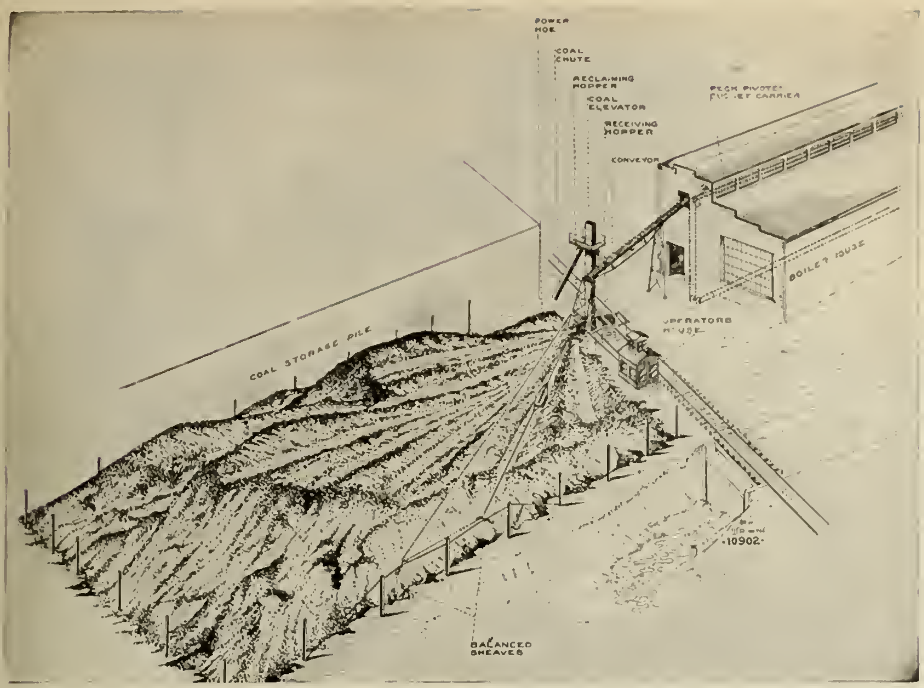
Heat Small Portion

Normally, fuel oil at ordinary temperature, is a heavy, inert, non-explosive fluid; crude oil may, however, contain a fair percentage of the lighter fractions which may vaporize and form an explosive mixture. Another danger arises from the use of steam coils to heat the heavier oils. These coils should be placed near the suction pipe so as to heat as small a portion of the tanks as possible. In any event, oil should never be heated above 140° F. Serious hazard sometimes arises from leaks due to careless handling, faulty tanks or piping.

A small leak allowed to continue may result in the formation and accumulation of explosive vapor in low levels, since it is heavier than air and subject to ignition by sparks, naked flames, smoking, etc. Spilled oil should be wiped up at once and drip pans emptied regularly. Leaky piping is especially dangerous as the oil is usually heated and under pressure. Such leaks may occur in the form of a spray which will have a greater tendency to mix with the surrounding air.

In fighting oil fires water must never

Crane with clamshell bucket.



Typical layout of storage using scraper and skip-hoist

be used as it will only tend to spread the burning oil over a greater area. Oil fires can be extinguished only by sand, steam smothering or chemical means. Tanks should be permanently equipped with steam or foam smothering connections.

Concrete Untried

Steel plate tanks are usually recommended to meet insurance and municipal regulations for the storage of oils in large quantities. Lately there has been considerable interest shown in the possibility of concrete as a material for tanks, due largely to the ease of construction and facility in obtaining raw materials.

A well developed fuel handling and storage system, in which both the coal and ash bunkers are located outside the building, was recently installed in an electric lighting plant. Skip hoists are used throughout, and a coal weigh larry carries the coal from the bunkers to the stokers. A cable drag scraper is used for coal storage.

Machinery is reduced to its simplest form, the equipment consisting of only a few self-contained units. Three winding machines are used, one for the coal skip, one for the ash skip, and one for the drag scraper. These are placed side by side in a clean, well lighted room in the coal house.

Coal is received at the plant in railroad cars and dropped into the track hoppers. From these hoppers the skip hoist is loaded by a loader of the self-damming type. By the use of this type of loader the skip bucket cannot be flooded or underloaded, insuring the skip hoist working at maximum capacity.

Opened by Bucket

The loader consists of a fixed chute or body bolted direct to the underside of the hopper. The chute has cast iron sides and a heavy steel plate bottom. To it is suspended a pivoted undercut gate built with cast steel sides and a heavy steel plate top and bottom. This pivoted gate is opened by the descending skip bucket coming in contact with, and pulling down, a spring hook attached to the chute, and is closed by the ascending skip bucket.

Counterweights are attached to the pivoted chute to assist in closing and keep it closed.

A balanced skip hoist is used in which one bucket acts as counterweight for the other, alternately loading, ascending, discharging and descending. The bucket is a simple, rectangular steel box, open at the top and fitted with flanged wheels and hoist bale. It is discharged by inverting on dump rails.

The entire operation of the skip hoist is automatic. The operator pushes a "starting" button, and the bucket ascends, accelerates to 250 ft. per minute, slows down and discharges at the top, lowers and reloads automatically and again ascends. This cycle is repeated entirely automatically and alternately by the two skip buckets until the "stop" button is pushed. The skip bucket discharges to a hopper which passes the coal into a feeder to be delivered to the crusher.

Passes Into Bunker

From the crusher the coal passes into the bunker, until the bunker is filled, after which it is chuted outside for storage. A 1,000-ton steel suspended bunker is used, with the outlet gates spaced close together to minimize "dead" coal.

From the bunker the coal is drawn into a ½-ton coal weigh larry, weighed and then discharged to the stokers as needed. The gates are spaced close together and the larry travels the full length of the bunker. By means of a recorder the larry operator is enabled to keep an accurate check on all coal consumed.

The coal which has been chuted for storage is stored out and reclaimed by a cable drag scraper at the rate of 80 tons per hour. The scraper is dragged back and forth over the coal, it being quickly detachable so it can be turned around to reclaim the coal. Around the edge of the yard are steel posts. To store coal at any portion of the storage yard, the tail blocks are changed from one post to another.

When reclaiming, the scraper is reversed on the cable and the coal is scraped back to the reclaiming hopper, and delivered to the skip hoist which will elevate the coal to the bunker. This system is used to store 10,000 tons at a depth of 6 feet.

Has Wide Field

Turning to the continuous conveying type, the belt conveyor is one of the oldest known devices and has a wide field of usefulness. It is practical to run these conveyors at relatively high speeds which adapts them well for conveying long distances. The three most important elements of a belt conveyor are the supporting idlers, the belt and the drive.

The earliest idlers were flat rollers but to-day the rollers are generally trough-shaped with a central horizontal roll and inclined side-rolls. The speed of these rolls is from 200 to 400 r. p. m.

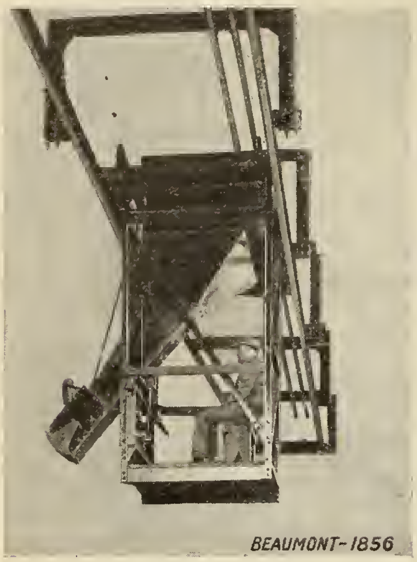
Belts for conveyors may be canvas or rubber. The belt should be flexible enough to conform to the trough by its own weight to get the guiding action of the central part of idler.

Belt conveyors are commonly driven at the head or discharge end; however,

500,000 ton storage plant

under some conditions they may have to be driven at the tail end, or intermediate point. Belt conveyors work best when the angle of inclination is less than 20°.

Another widely used type of continuous conveyor is the pivoted-bucket carrier. On horizontal or inclined runs, the rollers on the bucket-chain move along on standard T rails; on vertical runs they are confined to their path by double T rails for each chain. The buckets, usually of heavy steel although sometimes of cast iron, are pivoted and swing freely on rods, their weight with that of the material serving to keep them always in an upright or load carrying position. The material is discharged from the buckets by an automatic tripping device which may be fixed or movable.

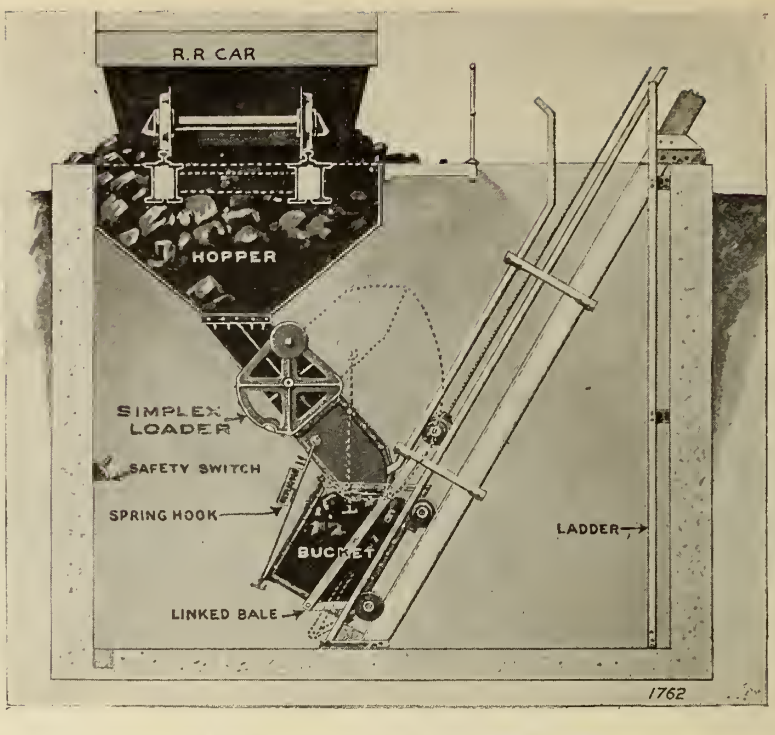


Coal Weighing Larry.

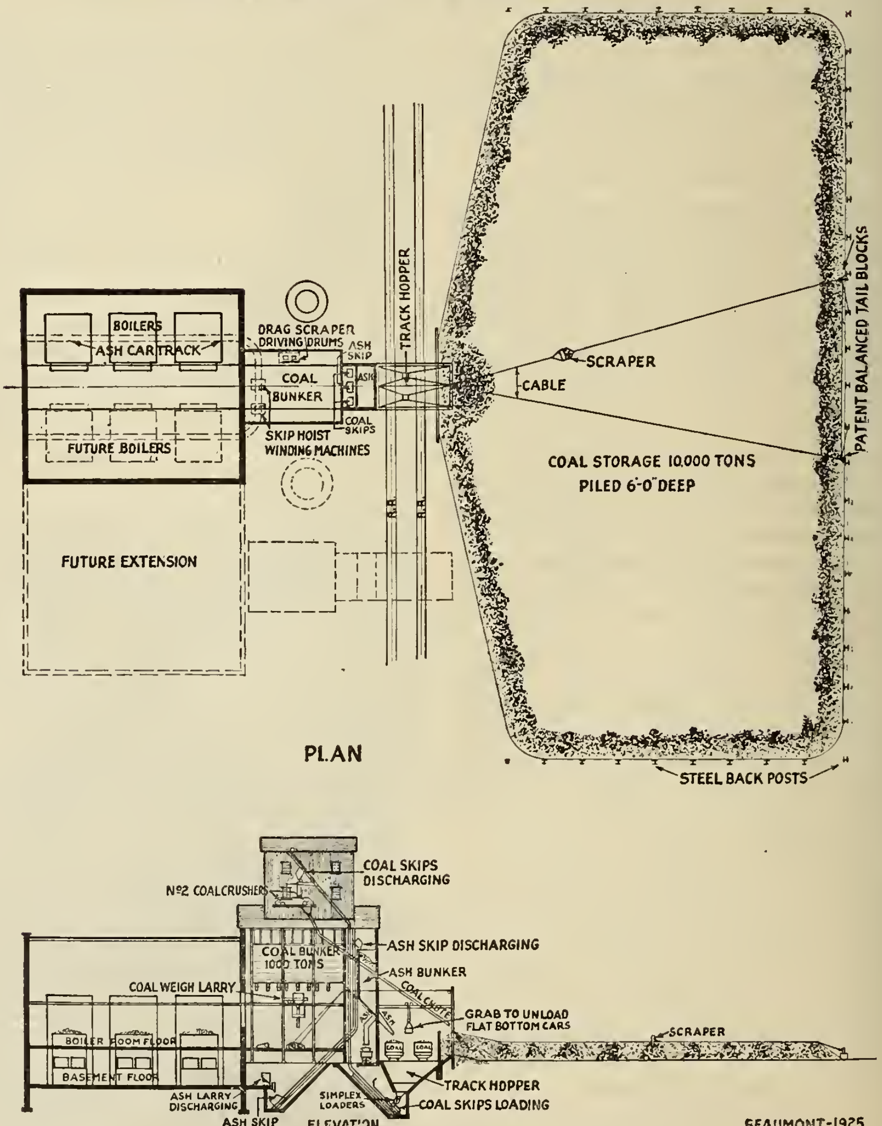
The speed of the buckets is slow, from 40 to 50 feet per minute. This type of conveyor is built in capacities of 15 to 300 tons per hour, the commonest type having a capacity of 40 to 100 tons per hour.

A small single-phase motor will continue to run in the direction in which it is started. If a split-phase winding is supplied for starting the connections of either the starting winding or the main field winding may be interchanged to reverse the direction of rotation.

Mechanical efficiency is a term intended to express the ratio of indicated horsepower to that available for doing work. Brake horsepower divided by indicated horsepower gives the mechanical efficiency. For small single-cylinder engines the mechanical efficiency may be as high as 4 per cent., or the friction 6 per cent. of the indicated power. For large compound engines the mechanical efficiency is sometimes as low as 80 per cent., or the friction 20 per cent. of the indicated power.



Coal Hopper and Automatic Skip-hoist Loader.



Typical Layout for Electric Lighting Plant.

Pulverized Fuel in Action in a Sugar Refinery

Officials of British Columbia Plant Desire Longer "Try Out" Before Giving an Opinion on the Economy in Operation and Maintenance of This Type of Fuel

By Geo. R. Archdeacon, A.M.I.E.E.

DISTINGUISHED as the largest sugar refinery in Western Canada, the B. C. Sugar Refining Co. also possesses a power plant unique in its application to the problems of combustion in so far at least as the Dominion is concerned.

Here the quest for cheap fuel has been persistent, for the plant has in turn burned coal, with hand firing and mechanical stokers, then oil fuel, and now a brave experiment is being made with pulverized coal.

The economy of the last method is of course a debatable matter, as engineers are by no means unanimous either in their praise or in their condemnation of the results obtained.

Await Longer "Try Out"

E. T. Rogers, the vice-president of the company, is quite non-committal on this point, and preferred to refrain from giving any opinion until he had had a longer period of "try out." The system has been in service scarcely three years, and as one of the determining factors is the cost of operation and maintenance, Mr. Rogers did not consider it would be quite fair to either side to express an opinion until enough time had elapsed to represent a reasonable amount of wear and tear on the machinery incidental to the preparation of the fuel before it can be burned.

There were two points, however, upon which Mr. Rogers was emphatic:

> That pulverized fuel is uneconomical in a small or medium size plant, and that pulverized fuel is uneconomical in the furnace of a return tube boiler.

Seven Separate Stages

The process of operation of the pulverized fuel system may be divided into separate stages as follows:

Storage of the "raw" coal.

Transporting the "raw" coal to the crusher and drier.

Transporting the partly dried fuel to the 2nd stage grinder.

From the grinder to a considerable height over the boilers.

Distributing to each boiler as required.

Methods of blowing through a nozzle with air mixture.

Ignition.

The fuel employed in this plant is a very low grade, fine slack, possessing a calorific value of about 10,000 B.t.u. This is landed from barges and dumped into a large coal bunker with a capacity of about 1,400 tons.

In the flooring of the bunker are a number of slots about 12 inches square. The coal falls through these slots to a conveyor, consisting of a high grade rubber belt about 24 inches wide and ½ an inch thick. This belt runs over a series of small "idler" pulleys inclined at an angle, so as to hollow out its contour and prevent excessive spillage.

View of boiler room and fuel feed control.

Carry Coal 500 Feet

The coal is conveyed in this manner a distance of about 500 ft., and elevated about 35 ft. It then makes its entrance to the drying building, a solid brick structure about 75 ft. long, 45 ft. wide, and 40 ft. high.

At one end, at an elevation of some 35 ft., is a platform running parallel to the belt conveyor. This permits of close inspection of the coal as it makes its way toward the crusher and drier.

It will be apparent that it is quite possible for metals or other foreign bodies to be mixed with the coal and conveyed with it. In the case of a piece of iron or steel having fallen in the coal during its progress from the mine to the crushing plant, it is important that its further progress should be arrested, as in the event of its finding its way into the crusher it would doubtless result in the destruction of the crusher, or at least in a stoppage of the process of crushing.

An Ingenious Device

To eliminate this contingency a most ingenious device has been provided.

At the end of the run of the conveyor, the belt passes over an end pulley and the contents of the belt are deposited into a bell-mouthed orifice, which leads into the crusher.

This end pulley is 3 ft. in diameter, and its surface is made of brass.

The pulley is hollow, and contains a powerful electro-magnet. There are two collector rings mounted on the spindle of this pulley, and through the brushes on these collector rings, is conveyed a supply of direct current at 110 volts which energizes the electro-magnet.

Should pieces of iron or steel accidentally be carried along the belt the electro-magnet attracts them and prevents them from falling into the crusher.

The coal is then free to pass into the grinder, falling out of the mesh into a rotary drier.

Motor-Driven Drier

This drier is 5 ft. in internal diameter and approximately 50 ft. long. It is supported on 2 sets of steel tires shrunk around its outer surface. The whole is rotated about 25 revolutions per minute, being driven by a 10 h.p. Canadian General Electric induction motor.

In the rotary drier are a number of narrow projections upon which the coal that has been crushed rests, until the position of the ledges is so changed as to dump the coal on to another ledge, when the operation is repeated.

A screw conveyor passes through the inside of the rotary drier, and as the partly dried coal is thrown from one ledge to another portions of it fall into this conveyor.

The middle section of this rotary drier, which occupies about 50% of its total length, passes through a furnace and, as the crushed coal is slowly tossed about inside the drier, the heat rapidly gains access to the coal, which is soon reduced to a dry powder.

The furnace used for this purpose is itself fired with pulverized fuel.

As the dry fuel leaves the drier it passes through an enclosed tunnel to the dry coal elevator, where it is dropped into a bucket elevator and taken from the drying building into an adjacent building, being elevated to a height of 60 ft., and distributed through two gates into 3 enclosed bins of 15 tons capacity each.

There are three pulverizers arranged on a platform about 10 ft. apart. Each can handle 4 tons of fuel per hour.

There are 6 boilers, and the screw conveyor is laid across the whole width of the tops of the boilers. The fuel is deposited into large "chutes," which are connected by a 4-inch pipe to the special mixing chamber, where the pulverized fuel and the air are mixed. From this mixing chamber the fuel is propelled by an air blast through a nozzle, in the form of a "spray" of coal—powder and air.

Ignited by Waste

This "spray" is ignited by the application of a piece of cotton waste soaked in oil.

With pulverized fuel it is necessary to provide a very large combustion chamber, and in this plant one sees the unusual spectacle of a boiler possessing two fire doors, one at the front end and the other at the back. This is necessary on account of the combustion chamber being so large that it is inconvenient to rake out the ashes from one end only.

In this particular installation it was found necessary to raise all the boilers from their former setting. This involved considerable expense and made the cost of the installation excessive.

It is important that this point should be borne in mind, as much structural alterations are unnecessary in the case of a new plant being installed.

In this plant the combustion chamber is 12 ft. x 20 ft. x 14 ft.

In the casing of the air mixing chamber leading to each projector nozzle are a number of slots regulated by a set of sliding doors so that the correct amount of air may be admitted to the fuel.

The fuel used in this plant shows an ash content of 27% to 30%. It must be understood that only the very lowest grade of coal is used.

The ash is raked out of the combustion chamber and drops into a tunnel at the side and front of the boiler. This tunnel runs down to the sea and a constant stream of salt water flushes it, freeing it of the ashes from the boilers. This salt water is the overflow from processes in the factory, and need not be considered an additional cost in the operation of the plant.

One of the most remarkable appliances indicative of the minute detail work entailed in the designing of the plant, is the cinder elimination process.

There is an induced draught fan in a sort of "by pass" near the top end of the main flue. This fan is 12 ft. in diameter, and it draws up all cinders, dust, and solid matter.

To prevent the accumulation of fine dust on the tubes of their boilers a complete system of Diamond Soot Blowers has been installed on each boiler.

The boiler plant is as follows:

2 B. & W. boilers, 250 h.p. each.

2 Sterling boilers, 500 h.p. each.

2 Badenheusen boilers, 500 h.p. each.

Pump room—

2 Weir feed water pumps.

De Laval centrifugal pump direct connected with a 50 h.p. Westinghouse Induction Motor.

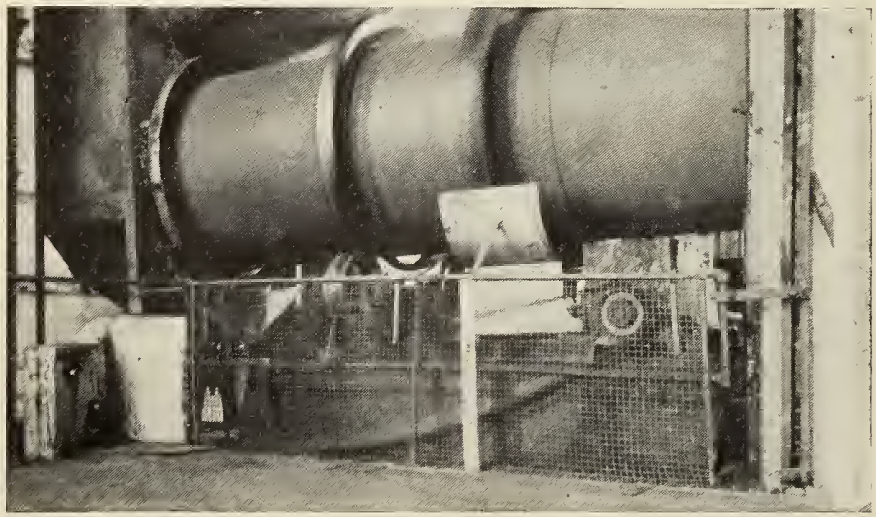
1 Northey ram pump.

This plant consumes over 100 tons of coal per day, therefore its daily consumption has assumed such proportions that a considerable capital expenditure may be warranted, if it results in a reasonable reduction in the cost of the daily fuel bill.

Price of Coal Unknown

Mr. Rogers, unfortunately, did not care to disclose the price he is at present paying for the low grade coal used, and as this is the crux of the whole matter when considered from the point of economy, the writer is entirely in the dark as to just how far the installation has justified itself.

Doubtless the reduction in the actual purchase price of the low grade coal is of substantial proportions.



Rotary Drier.

PIPE LINES

Grunting of an engine is frequently caused by the vibration of the piston rings when they have a trifle too much play between the bullrings. The trouble can partly, if not wholly, be remedied by putting in a set of stiffer piston-ring springs.

Education is the feed water heater of your personal energy—utilizing waste time.

Burnt oil may be cleaned from the cylinder head of an engine by using strong lye-water, and after it is cleaned paraffin rubbed over the surface will keep it bright.

Get the habit of writing down your questions and answers problems. We'll help you answer them.

If an engine is pounding, in searching for the cause of the trouble do not attempt to remedy it too soon. If it is apparent that keying-up is required, do not key too tightly and try to do it all at once, as the crankpin or crankshaft may be flat on one side and there is danger of getting a hot bearing or brasses.

There is always something wrong with a man, as there is with a motor, when he knocks continually.

Follower bolts lose their strength by crystallization, caused by alternate cooling and heating, and are likely to cause fracture when comparatively small strains are brought to bear. To be on the safe side careful engineers make a practice of renewing these bolts at certain intervals.

Luck in fishing is like luck in getting orders—ten per cent. in knowing where to go, ninety per cent. in going there.

Before starting a rotary converter open the field-breakup switch; if this is closed during starting, a dangerous voltage will be developed.

The engineer without a purpose is like a ship without a rudder—a waif, a nothing, a no man.

After a commutator has been turned up in a lathe, it should be carefully inspected to see that the tool has not drawn the copper from one segment to the next across the mica, thus causing a short circuit.

A reliable grease may be made from good cylinder oil and tallow or tallow soap mixed to suit.

Projected area of a bearing is equal to the diameter of the shaft multiplied by the length of the bearing.

Engine cylinders should be inspected at regular intervals so as to ascertain whether the piston has lost its proper alignment by wear or other causes, to determine if the cylinder has been cut, if the follower bolts are secure and free from fracture or if shoulders have been formed on the ends of the cylinder from improper lining of the connecting rod.

Economical Drive of Power Station Auxiliaries

Expenditures Justified in Central Supply Plants Feeding Important Industrial Areas Extravagant in Case of Stand-by Stations Used Only at Infrequent Intervals

By L. BREACH, I.E.E., and H. MIDGLEY, B.Sc.

THE general question of the drive of power station auxiliaries is one which to-day is receiving an increasing amount of attention from up-to-date enigneers.

In the case of the pioneer plants, consisting of boilers with natural draught and hand stoking, supplying steam to simple condensing reciprocating engines, with condenser pumps coupled mechanically to the main engines, practically the only auxiliaries requiring a separate drive were the feed pumps, which were usually of the steam-driven reciprocating type.

At the present time, however, auxiliaries of power plants require a large amount of thought and attention from the designing engineer, and it is therefore proposed to consider a few of the points to be watched when arrangements for a new power station are being made.

When preparing a scheme for the auxiliaries, one of the first questions which arises is as to the purpose of the station, that is, whether it is for constant running on a high load factor, whether it is for an ordinary commercial load, or whether it may only have to run a few hours in the year, as in the case of a station which acts as a stand-by to a hydro-electric supply.

Find Decisive Factor

In other words it is essential to know whether continuity of supply or simplicity of design is the more important factor, for it is obvious that an expenditure on auxiliaries which would be justified in the case of a central supply station, feeding an important industrial area, would be extravagant in the case of a stand-by station to be used only at infrequent intervals.

It should therefore be noted that only a modern station equipped with large turbo-alternators and mechanical stokers is dealt with in this article, and attention has been confined to the supply of power for the auxiliaries, no attempt having been made to include in the discussion evaporators, ejectors and similar equipment.

It is, of course, obvious that it is very difficult to lay down any general rules as to which is the best system of auxiliary supply, for there are many cases where alternative schemes are technically equal, and the choice may quite well be based on the likes and dislikes of the engineer who will be responsible for the satisfactory operation of the station.

3 Aspects of Problem

It is proposed, therefore, to deal with three main aspects of the problem and to outline the most important features of these aspects, which are as follows:

The consideration of the different types of auxiliaries which may be used in a station, and their individual requirements and relative importance.

The consideration of the different types of supplies available for the auxiliaries.

The consideration of the suitability of different combinations of auxiliaries and supplies under different conditions of station working.

For the purpose of considering alternative systems of drive, the auxiliaries in a power station may be grouped according to the length of time during which they may be shut down without causing serious inconvenience and even damage, and this time depends upon:

The importance of keeping the station on load without intermission and,

The importance of keeping the individual turbo-alternators on load without intermission.

Avoid Vacuum Loss

It may be taken as an axiom that in a large power station with turbo-alternators each of not less than 10,000 kw. capacity, loss of vacuum must at all costs be avoided, not only because of the fact that the output falls by about 60 per cent. when the turbine exhausts to atmosphere, but more important still, because the rise of temperature of the blades at the low-pressure end, consequent upon the heat from the windage losses, may cause serious distortion and damage.

We may therefore divide the auxiliaries into four types:

(a) Those which must not on any account stop. This includes the main circulating water supply, the air extraction, and station lighting.

(b) Those which must not stop for more than, say, 60 seconds. This includes the boiler feed pump, and the power for the control circuits.

(c) Those which may stop for five minutes, but not longer. This includes water extraction, individual stokers, individual forced-draught and induced-draught fans, and ventilating fans.

(d) Those which may stop for a period of 12 hours without shutting down the station. This includes coal and ash conveyors, coal crushers, pumps for water-softening plants, and economizer-scraper motors.

Gravity Flow of Water

Type (a).—Unless the flow of circulating water through the condenser tubes is due, in whole or in part, to gravity, it is evident that a stoppage of the circulating water pump will mean a stoppage of the flow of circulating water. As the full-load input of steam would boil the water contained in the tubes in about 50 seconds, a stoppage of the circulating pump consequently means an immediate loss of vacuum.

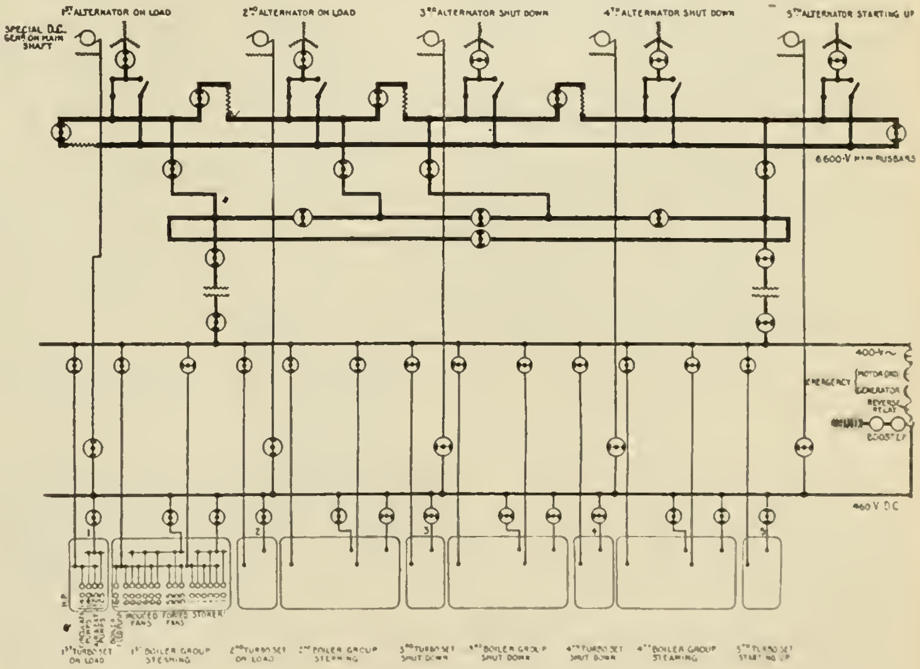


Figure One.

That a loss of vacuum will at once follow a stoppage of the air extraction is a self-evident fact.

The only way to ensure continuity of supply for these duties is to have pumps in duplicate, each of sufficient size to carry the load without too great a loss of vacuum, and drive each pump of the pair from a totally different supply.

It is, of course, possible that both supplies might fail at the same time, but, if the sources of supply are kept absolutely independent, the chances of this are so slight that for all practical purposes such duplication may be considered to give continuity of supply.

For example, one pump steam-driven and the other driven by a motor supplied from the main busbars would satisfy the requirements, but one pump driven by an a.c. motor fed from the main busbars through a transformer, and the other pump driven by a d.c. motor obtaining its supply from a rotary converter supplied through a transformer also from the same section of the main busbars, would not be a good example of duplication, as a fault on that section of the main busbars might shut down both the a.c. and d.c. supplies.

Type (b).—The classification of the boiler feed-pump under this section is consequent upon the high rates of evaporation now obtained in water-tube boilers, in which the water-level will fall to a dangerous degree if the feed supply fails for more than about a minute when the boilers are on full load.

Must Guard Supply

This group of auxiliaries must be so arranged that in the event of a failure of supply, another is immediately available. For the boiler feed-pumps one of the most suitable schemes is to have one motor-driven rotary pump and one steam-driven rotary pump for each group of boilers, either pump alone being capable of feeding the group, the pump which is not on load being always kept ready for immediate use.

Type (c).—For the auxiliaries of this class an alternative supply must be readily available, but it need not be immediately available, a suitable arrangement being to have this type of auxiliaries so arranged that they may all be fed from either of two alternative supplies, the change-over being effected when required, by means of selector switches, the motors being first shut down and then started up again on the new supply.

Avoid Lengthy Shut-downs

Type (d).—In this case the usual practice is to carry spares for such parts are as likely to cause trouble, e. g., motor armatures. These can be installed without entailing a shut-down of more than a few hours, during which time the auxiliary can be dispensed with. It will be obvious that in the case of coal-conveyor motors, for instance, it should be possible to rely on the supply in the service bunkers for such time as is required to replace the armature of the motor.

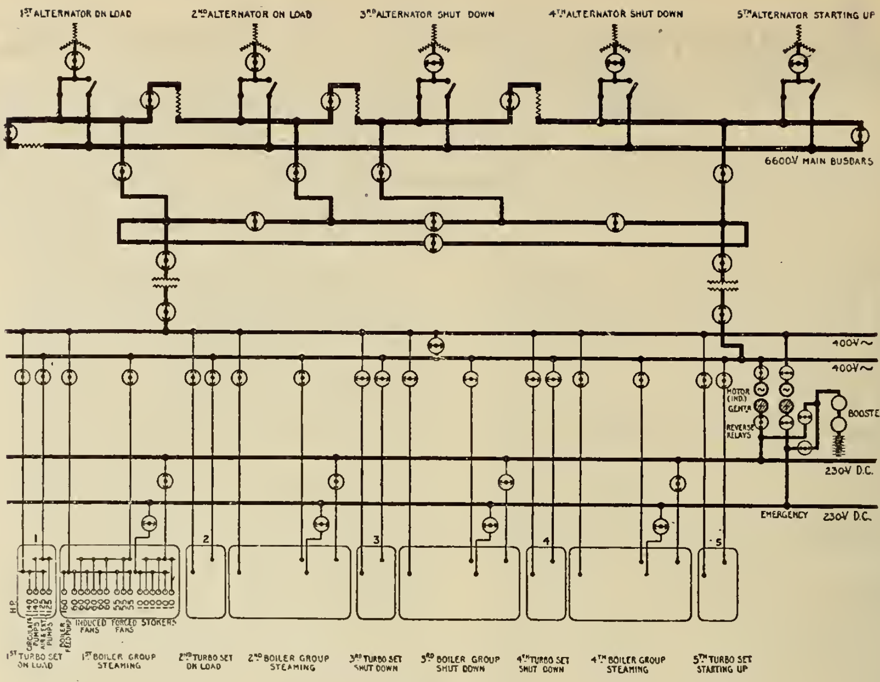

Figure Two.

There are many types of auxiliary supply, the following being the more important:

(A) Direct steam drive.

(B) Electric, from main alternators via high-tension busbars.

(C) Electric, from main alternators direct.

(D) Electric, from main alternators via special windings on main transformers.

(E) Electric, from special steam-driven a.c. or d.c. generator (house set).

(F) Electric, from special a.c. or d.c. generator on shaft of main turbo-alternator.

In the author's opinion, the question of cost should be considered only when absolute reliability has been assured, and if there is any difference in reliability between the alternatives the costs should not affect the decision.

Fear False Economy

After all, the cost of the auxiliary plant is only about 5 per cent. of the total cost of a new station, and it would appear to be false economy to jeopardize continuity of supply through any saving which might be made in the first cost of such plant.

A few of the more important features alternative supplies may with advantage be noted.

A. Direct steam drive.—This may be by either turbine or engine. On the whole, direct steam drive requires more attention than electric drive, but it has the advantage of being absolutely independent of any disturbances on the electrical system. For any except very small sizes the engine type need not be considered, but the turbine either direct-coupled or geared fills a very useful place.

Of course, at times of heavy load, if the main steam pressure falls, the power and speed of direct steam-driven auxiliaries will fall just when they may be most needed; this is especially the case where an auxiliary turbine driving a main circulating pump exhausts into one of the main turbines near the low-pressure end, for under the heavy-load condition the back pressure in the main set rises, with a consequent increase of steam consumption and fall of speed of the auxiliary turbine.

Keep Joints Tight

A considerable amount of attention is required to keep tight the many steam-pipe joints entailed with direct steam auxiliaries, and the overall thermal efficiency of the station is reduced by the heat losses due to increased radiation surfaces, etc. Further (and now that the importance of really pure de-aerated feed water is being more and more realized, this is a matter of considerable weight), the use of direct steam drive increases the make-up to almost double, the experience of one Canadian supply company being that the adoption of electrically driven auxiliaries reduced the make-up of the total boiler feed in circulation from 6 per cent. to 3 per cent.

The one auxiliary for which direct steam drive is especially suitable is the boiler feed-pump, the exhaust steam being utilized to heat the feed water, this being particularly convenient when, for any reason, the main feed-heating arrangements are out of action.

B. Electric drive from main alternator via H. T. busbars.—This auxiliary supply, if alternating current, may be at the busbar voltage or reduced by means of transformers, whilst in the case of direct current the voltage may be whatever is found convenient. Now that the building of a. c. motors of more than 50 h.p. at voltages higher than 400/500 is a matter of little difficulty, the use of the main generation voltage, or at any rate a voltage of the order of 3,000, merits careful consideration.

See Little Advantage

Assuming the main generation voltage to be 6,600, this would be too high for any motors except those for the main circulating-pumps. A pressure of 3,000 volts would be suitable for the main circulating-pump motors, the air-pump and extraction-pump motors (where these latter pumps are both driven by the same motor), and the boiler feed-pump motor, but there appears to be little advantage in stepping down to this pressure. In view of the extra cost of the insulation for 3,000 volts above the more usual voltage of 400, once it has been decided to step down for the auxiliaries it seems just as suitable to step right down to 400 volts for all motors rather than introduce another voltage intermediate between that and the main generation voltage.

Alternating current versus direct current for auxiliary motors.—This is a very much discussed question, and a few remarks on the factors affecting the choice may be of interest.

Direct-current motors require frequent attention to the commutating gear to avoid sparking, and although they are often seen running without any apparent trouble in an atmosphere full of grit and dust, nevertheless the d. c. motor requires more attention than the a. c. motor.

D. C. Motor Advantages

Direct-current motors can be economically subjected to speed regulation over a wide range and, perhaps most important of all, they can be run off a battery in times of breakdown or other emergency.

The greatest disadvantage of a.c. motors lies in the fact that speed regulation is not an economical proposition. Of course the speed of a slip-ring motor can be varied over a small range by varying the resistance in the rotor circuit, but this is a very wasteful method, and the system of having a controller to alter the connections of the stator windings and so alter the number of poles, is only suitable for three or four speeds at the most. Variable-speed motors working on the "cascade" principle might be used, but these give only a limited number of speeds, which are fixed by the number of poles. As final regulation must therefore be obtained by the use of valves or dampers, there is no advantage in the installation of this type of motor as compared with the ordinary asynchronous type.

On the other hand, in the case of pumps and fans, which form a very large proportion of power station auxiliaries, the output can be reduced by throttling, i.e., by control with valves or dampers.

Need Less Attention

Alternating-current motors, of course, require much less attention than direct-current motors, especially, if, in the case of slip-ring motors, brush-lifting gear is fitted. They can run for very long periods without attention, and without having to be stopped for examination.

C. Electric supply taken direct from machine terminals.—This scheme was at one time very popular with one well-known firm of consulting engineers, the main advantage being that in the event of one of the main generator switches being opened the auxiliary supply is not cut off.

D. Electric supply from main alternator via special windings on main transformers.—This arrangement is only suitable for a station in which the step-up transformers are directly coupled to their respective turbo-alternators, and the switching is carried out on the high-voltage side.

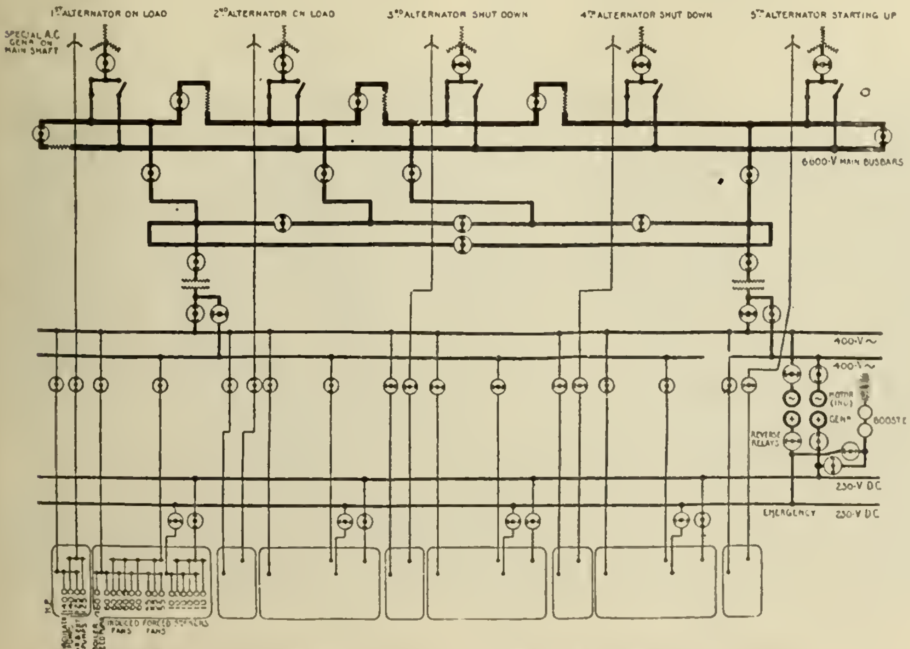

FIG. 3.

E. Electric supply from special house set.—This is undoubtedly the most popular system of auxiliary electric supply in Britain but there is considerable diversity in the disposal of the exhaust steam from the house turbine.

This steam may be taken:

(a) To atmosphere.

(b) To a stage of the main turbine near the exhaust end.

(c) Direct to the condenser of the main turbine.

(d) To a feed heater.

(e) To its own condenser.

Wasteful of Water

(a) Direct exhaust to atmosphere is uneconomical and very wasteful of water, but it is simple. For emergency use it is worthy of consideration.

(b) The disadvantages of exhausting to a stage of the main turbine near the low-pressure end have already been mentioned.

(c) Exhausting to the main condenser suffers from the same disadvantages as exhausting to a stage near the low-pressure end of the main turbine.

(d) Exhausting to a feed heater is a system which has been installed in several Canadian and American power stations. As the purpose of a house-turbine is not to feed heat, but to generate power for the auxiliaries, and as the use of steam bled from the main turbine for feed heating has been found to be both economical and satisfactory in working, it would appear advantageous to dissociate the house set from the duty of feed heating.

(e) A house set exhausting to its own condenser gives an arrangement which is efficient and self-contained but somewhat complicated and, whilst it has many advantages, it entails an increase in the amount of running machinery in the station, a feature to be avoided as far as possible. This scheme may also entail an increase in the operating force.

Whether the house turbine is installed for the auxiliaries of each main set or whether one house set is installed for the whole station, is largely a matter of opinion. In the case of a station in which for long periods only one main turbo-alternator is on load, one house set per main turbine would possibly be more economical in steam consumption, but on the other hand the capital cost of this proposition is much greater than that of the other, and the authors are of the opinion that, where house sets are adopted, it is better to have two per station, one on local and the other for stand-by purposes.

Wins Operator's Favor

F. Special generator on the main alternator shaft.—This is a comparatively recent proposal and appears to have much to commend it from the operating point of view, as the supply from it is totally independent of any faults on the main supply and the only possible source of trouble is internal.

Whether it should be a.c. or d.c. is open to discussion. If d.c. it would be

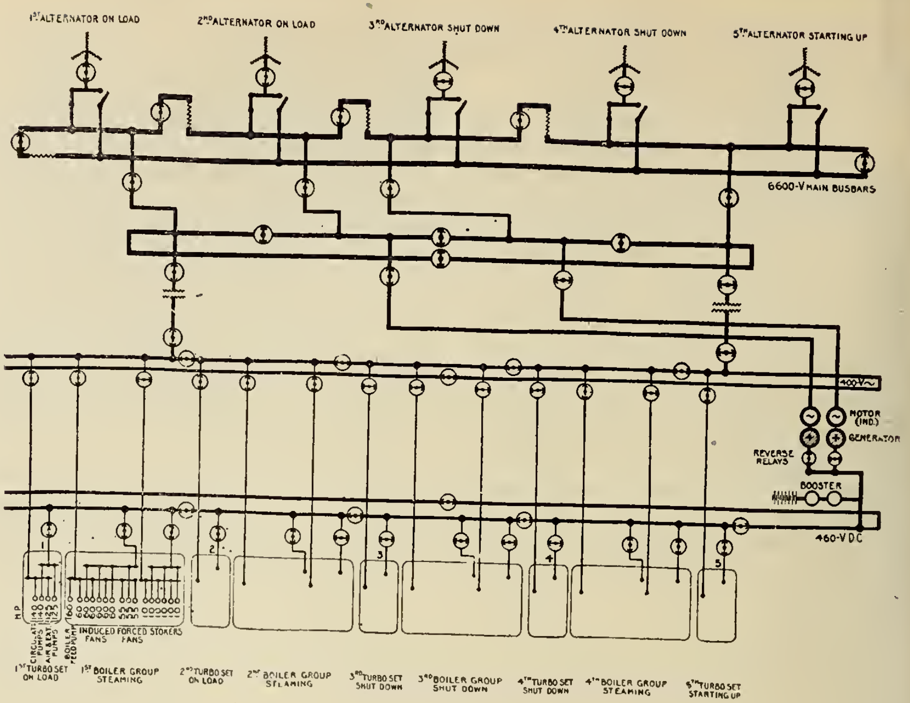

FIG. 4.

run in parallel with the other d. c. plant and the battery which is available for emergencies, and of course a certain number of d.c. auxiliary motors with the advantages previously mentioned are required; if a.c. it could no longer be used directly in parallel, but a simpler machine results, and it is a question for the manufacturers as to whether a d.c. generator, of say 300 kw. and 3,000 r.p.m. in the case of a 16,000 kw. turbo-alternator, and of 450 kw. at 1,500 r.p.m. in the case of a 25,000 kw. turbo-alternator, could be satisfactorily constructed. The excitation of an a.c. generator is a matter of consideration. It might be excited in parallel with the main alternator, but, in view of the facts that main field rheostats are now practically obsolete, and that voltage regulation is carried out by adjustment of the exciter field, it will be necessary either to have a special field rheostat for this alternator or allow its voltages to vary with the alterations in the exciter field, due to the action of the automatic voltage regulator which is governed by the main busbar voltage.

May Utilize Battery

As an alternative, the excitation current of the special alternator may be drawn from the battery. This is perhaps the best way.

Conditions of station.—In addition to the internal arrangements, the conditions of the station must be taken into account when the auxiliaries are being decided.

Stations may be divided into the following classes:

(1) Isolated, supplying an area or an individual works.

(2) One of several supplying an area, but not permanently linked up.

(3) One of several stations supplying an area, and permanently linked up.

(4) A station used as a stand-by (usually to a hydro-electric supply).

In the case of a station of Type (1) or (2), the arrangement of auxiliaries depends upon the importance of continuity of supply. For instance, where the station supplies a works with a large number of interlinking processes, continuity of supply is of primary importance, and in such a case it is essential to see that this continuity is not prejudiced through false economy in the layout of the auxiliary arrangements.

Devise 4 Schemes

The various auxiliary supplies discussed can best be compared by the examination of definite schemes for a station supply, these schemes containing alternative combinations of the different supplies. With this object a few arrangements, drawn out with a view of showing possible rather than recommended proposals, have been prepared by the authors.

The alternative schemes are designed for a station containing five 25,000 kw. turbo-alternators, of which four would be required for maximum load. Steam would be obtained from four boiler houses, one boiler house supplying full-load steam for one turbine. Each boiler house would contain six boilers, five of which would be required for the maximum output of one turbine. This allows one boiler per group always to be laid aside for cleaning.

Each turbine has two separate circulating pumps, each with its own motor, and two air and two extraction pumps, there being two motors for these, each motor driving one air and one extraction pump. An alternative is to drive each air and extraction pump by its own motor, but if each of these pumps is to be in duplicate this necessitates four motors instead of two and, providing the speed of the pumps is suitable, the arrangement put forward appears to be less expensive and equally reliable.

Treated as Units

It will be seen that, generally speaking, each set of turbo auxiliaries is independent of the others, so that it can be trusted as a unit; similarly, the group of boilers required for one turbine forms a unit which is independent of the others, although in emergency any boiler group can be used to supply steam to any turbine.

The use of two circulating, two air and two extraction pumps is, from consideration of design, practically essential for 25,000 kw. sets, but for smaller sizes of turbo-alternators the case is different, and one very usual scheme is to have two circulating pumps for the condensers or two turbines, each pump capable of supplying circulating water for one condenser, but running in parallel on the water side, so that in the event of failure of one pump it is certain that each condenser will have a supply of cooling water adequate to maintain a considerable percentage of the normal vacuum until such time as the trouble can be rectified or one of the turbines shut down. The two pump motors are fed from independent sources, and valves are installed for the isolation, when necessary, of either pump, all these valves being open under normal conditions.

One Drawback Seen

The main drawback to this proposal is that to obtain a duplicate auxiliary supply it is essential either to run the turbines always in pairs, or for one turbine to run pumps of twice the necessary output.

At this stage it may be of interest to consider a scheme adopted in some Canadian and American stations of having the boiler house auxiliaries direct steam-driven, and installing a special d.c. generator for the condenser auxiliaries. This generator is driven at one end by a turbine exhausting to a feed heater, and at the other by an a.c. motor fed from the main busbars. Undoubtedly this gives for the turbine auxiliaries a drive which is unaffected by faults on the main busbars, but, in view of the possibility of failure of the generator, it does not assure absolute duplication of auxiliary supply. It is understood that such an arrangement is installed also for the purpose of regulating the feed temperature. Where it is adopted, care must be taken so that in the event of a fall in frequency of the main supply there is no danger of the motor on the generator shaft acting as a generator and overloading the driving turbine at the other end to such an extent that it is endeavoring to carry the whole station load.

Basis of Motor Power

The powers given for the various auxiliary motors are based on the assumption that the station is a riverside station, with a syphonic circulating system. If it were a cooling-tower station, the circulating-pump powers would be approximately doubled, but the air-pump

Alberta Heating Engineers Hold Convention

Representatives From All Parts of Province Discuss Modern Installations and Methods of Raising Standards at Enthusiastic Gathering—Hot Water Forced Circulation

ONE of the most successful and enthusiastic conventions which the West has seen for some time was the annual gathering of the Alberta Association of Heating Engineers at Medicine Hat. That the province has a real quota of live and well-informed engineers in this field was strikingly shown not only by the attendance but by the quality of the discussion and the type of address given.

It was apparent that the aim of the whole organization was to keep in touch with modern development in heating equipment and installation, and to give to the public a service incapable of being excelled elsewhere.

Due to the unavoidable absence of the president, R. J. Priestly, the sessions of the conference were presided over by Vice-President C. R. Frost. The first official act of the convention was the receipt of the freedom of the city from Mayor Huckvale. In a short address, the Mayor spoke of his delight in welcoming so many men whose profession was the raising of the standard of health and comfort in the homes of the citizens.

During the course of the convention interesting and instructive addresses were delivered by G. R. Taylor, R.P.E., Superintendent of Utilities at Medicine Hat; S. E. Whiteside, Sanitary Inspector of Medicine Hat, and by L. A. Willison.

Officers

The results of the elections of the officers for the Association for the next year were:

President—C. R. Frost (accl.)
Vice-President—G. W. Henderson.
Sec.-Treas.—W. H. Kelcher (accl.)

Executive Officers

H. J. Ferris, Edmonton.
J. H. Hillier, Calgary.

Chairmen of Committees

Sanitary—D. Campbell.
Heating—R. J. Priestly.
Legislative—W. H. Kelcher.
Apprenticeship—Jas. Carver, J. H. Hay.
Essay—H. Ferris.

In an address before the convention, W. B. Trotter, A. M. I. C. E., discussing Hot Water Heating by Forced Circulation, said:

There are several advantages claimed for the forced hot water system of heating, the first is, that the temperature of the heating surfaces in the building or buildings is at all times under the direct control of the operator and can be varied over a wide range at short notice so that weather conditions can be accurately provided for.

Advantages

If for instance, a chinook springs up all that is necessary is to stop the pump in addition to shutting down the source of the heat, and no excess of heat will be thrown into the building to be dissipated by means of open windows or otherwise. Secondly, a wider range of radiator temperatures is possible than with steam systems; also that no specialties are required, no thermostat, traps, modulation or temperature control apparatus, etc., so that the upkeep is low.

Owing to the small sized piping required, the cost of the pipe work is moderate, while as fairly high temperature can be carried in the radiators if required; on excessively cold days radiation need not be figured for more than average cold conditions.

Types of Systems

While the system may be divided into two parts, the trunk distributing mains and the buildings, there are two distinct systems that can be utilized in both cases: the circuit system and the two pipe system; either system may be open or closed. If the buildings are heated from a central plant and are strung out in a line the two pipe system would be indicated, but if they were placed so that a loop could conveniently handle them all, then the circuit system would be the most economical. In a two pipe system the mains are reduced as the connections are taken off, while in the circuit system, one pipe only is used, and both supply and return connection are taken off this pipe which is full size throughout. The supply on a loop system is usually run from the top and the return into the side of the same pipe. Installation costs are less with the circuit system, also frictional losses are lower.

Application

In the individual buildings a circuit system will often be found the most economical to lay out; in this case the risers and ground floor radiators are usually taken off the mains separately, in all cases long sweep bends are used.

Two pipe work can be laid out according to usual gravity practice, but with pipe sizes as given later, and if possible, a two pipe job should be on the balanced principle, so as to give approximately the same drop in pressure between any parts of the system so that no further

Heating Engineers in Convention at Medicine Hat.

balancing will be necessary. An overhead system with one pipe drop risers makes a very economical lay out.

It must be remembered that an additional advantage of forced hot water is that grades are of no importance, but of course a job graded, as is usual in gravity practice, will run longer with the pump stopped than a job in which there are numerous rises and dips.

Control

As the temperature of the radiators is usually controlled to suit weather conditions as previously mentioned it is not thought necessary to control each individual radiator with a hand valve, but they are often connected in batteries of three with one valve to the battery, making a saving in the cost of riser connections. The connecting piping between individual radiators should be the full size of the tapping, 2 inch. If individual radiators should need control on a loop this can be done as indicated. In two pipe work, if a number of radiators are likely to be shut off at any one time, and so increase the back pressure on the pump, a shunt is provided for. In a circuit or a two pipe system, radiators can be connected below the mains if required and will circulate perfectly. If a large circuit is taken off a one pipe main circuit, a shunt should be provided to balance the pressure.

Pipe Sizes

To obtain pipe sizes it is necessary to know the amount of water that will be pumped, and this will vary. Usually from 6 to 10 lbs. per sq. foot of radiation per hour is sufficient as an average, say one U. S. gallon per sq. foot per hour. As pump capacities are cataloged in U. S. gallons, this is a convenient figure. Where valves are provided on all branches and are carefully regulated the lower figure would be safe while other jobs may run as high as 14 lbs. Of course the temperature drop will be greater; for instance: Assume efficiency of radiator 180 B. T. U. per sq. foot per hour, dividing by 8-1/3 lbs. of water per sq. foot per hour will give a temperature drop of 21.5 degrees which is reasonable.

Velocity

In trunk mains assume 8 to 10 feet per second; circuit mains can be loaded up to 12 feet per second if necessary, smaller pipes in the building say 5 feet per second.

The following is safe:

4 in. pipe, 300 feet per minute.
5 in. pipe, 350 feet per minute.
6 in. pipe, 400 feet per minute.
8 in. pipe, 500 feet per minute.
1½ in. pipe will carry 2,000 ft.
2 in. pipe will carry 4,500 ft.
2½ in. pipe will carry 6,000 ft.

Then, the quantity being known, Area of Pipe (sq. ft.) equals:

$$\frac{\text{Wt. of water in lbs. per hour.}}{\text{V. F. P. M.} \times 60 \times 60.3 \text{ (density at 180°)}}$$

In a distributing system the branches to the different buildings from the trunk mains can be smaller than the mains in the building, but mains in building itself will be usual size.

After laying out the system the pipe sizes can be fixed tentatively from the following tables and then can be checked for frictional resistance. If the frictional resistance is too high larger pipes are indicated.

> **A steam leak is in reality the same as a hole in the power plant pocket book. Were the holes in our pants pocket we would promptly have them repaired before too much money was lost. Unfortunately it is often not so with leaks in steam pipes. It is hard to realize that a little wisp of steam or dripping water may be an important factor in loss, a factor which can be directly measured in pounds of fuel. Such wastes are far more tangible and more easily corrected than are certain of the more obtuse operating methods that a few engineers seem prone to consider of importance.**

Sizes	One Pipe	Two Pipe
½	0	45
¾	25	100
1	100	225
1¼	350	450
1½	500	660
2	1000	1300
2½	4000	2500
3	6000	3850
4	12000	8400
5	20000	15000
6	30000	23000
8	45000	30000

Friction

Friction: when the quantity of water and size of pipe are known, friction loss per 100 feet pipe is:

$$\frac{0.33 \times \text{V. } 1.86 \text{ (in ft. per sec.)}}{10 \times \text{D } 1.25 \text{ (in feet)}}$$

Valves on mains should be O. S. & Y. so that the control is indicated at a glance. Radiator valves can be any good valve with a good packing nut.

Branches should be valved perfectly, with lock and shield type gate valve where likely to be tampered with.

The end of mains should be vented the expansion tank where possible; this saves time filling the system.

Heater

Figure size of heater from gallons pumped as before, and estimate a temperature drop on a large central station of 30 degrees, but 20 degrees is ample for ordinary conditions.

Means; (1) direct heat of boiler. If this is used boiler should be cast iron type. (2) Waste heat from boiler, viz., economiser, but this apparatus is expensive in up-keep. (3) Exhaust or linesteam heaters; frequently one of each; two means of heating should always be provided. One pound exhaust steam should heat 28 lbs. water, 180 feed radiation per boiler horse power. Heater should be vertical or horizontal, 2 or 4 pass type.

Control Apparatus

Air controlled thermostat dial type, or expanding liquid thermostat, should be used.

Gauges.—On supply and return.

Thermometers.—On supply and return —30—260. Also thermometer for outside temperature and possibly a wind anemometer, are useful.

Pumps

Figure frictional losses carefully; feet head loss per 100 feet of pipe equals:

$$\frac{0.32 \text{ V } 1.86 \text{ (feet per second as before),}}{10 \text{ D } 1.25 \text{ (in feet)}}$$

but tables are available for frictional losses in all sizes of pipe carrying different capacities.

Type:—Horizontal split case single stage pump, turbine or motor driven. For capacity and head as calculated, average efficiency 70 per cent.

Expansion Tank

Radiation will carry 1½ pints of water per sq. foot. Double this, and to this allow for mains, and add trunk mains to arrive at the amount of water in the system. Capacity of tank should be 2 to 5 per cent. of the total water in the system. Tank can be closed pnuematic type in engine room, or open type in attic of building. The tank should be fitted with an automatic water feeder and a gauge glass.

Temperature

Closed system 240 degrees Fah. is maximum.

Open system 210 degrees Fah. is maximum.

Design of piping should provide for expansion and contraction due to high temperatures used. Hangers should be devised to hold weight of water and pipe. Use long sweep pipe bends at all changes of direction of mains.

Announcements

For the new Ford plant at Ford, Ont., the Combustion Engineering Corporation are making good progress in the installation of a fuel pulverizing plant which will be equipped with three 1,000-horsepower units. Three McAleenan boilers are being installed.

British trade generally keeps improving, despite disputes brewing in the industrial, shipping, and railway world. Iron and steel prices reached a peak in April. The week ending April 14 saw record coal shipments. Production reached 5,776,600 tons. Fifteen vessels aggregating 51,531 tons, were launched by Clyde builders during the month.

Editorial Comment

CAMPBELL BRADSHAW, Editor

Coal Storage Economy

ON EVERY hand it is the consensus of opinion that much can be done to overcome irregular demand by encouraging the storage of fuel, and in the case of coal no one can stress too strongly the great advantage of such action during the spring and summer for winter and fall use.

This recommendation should apply to all consumers of coal—railroads, public utilities, industries, and the home—and on the measure in which it is adopted will largely depend the evenness of distribution and the cost of coal to the public during the season of heavy consumption.

Fuel storage, adopted by the consumer, large and small, would benefit the carrier systems of the Dominion by equalizing their load. It would have the effect of reducing the cost to the consumer for it must not be forgotten that only for short periods since 1918 has the price of coal been closely related to the cost of production. It has been controlled by its availability in the market, which has depended upon and been influenced by various interruptions to the process of distribution.

In connection with distribution for the homes it may be pertinent to ask Sir Henry Thornton, at a time when the taxpayers of Canada are paying around $60,000,000 a year into the Dominion treasury to meet deficits on the C. N. R., what further loss would be incurred if a $6 rate were offered on Alberta coal to Toronto and Montreal in place of the $9 rate demanded "as profitable."

Mr. Thornton is losing sight of the fact that more than $12,000,000 of Ontario money alone is going out of the Dominion annually to the United States to pay for the anthracite the province buys there. Anything which will increase the supply and lower the cost thereof tends toward a reduction in the cost of living generally, and means a greater purchasing power for the wage earner himself.

Going Down Hill

THERE is an impression that because the engineer is the most important piece of "machinery" in a power plant he is the only man who can conserve fuel, and that the only place he can save it is in the place where fuel is used—the boiler room. Indeed, little effort has been made in the past to save fuel anywhere else.

There are, of course, many opportunities for saving fuel by efficient firing and good boiler room methods, but there is as large a field for fuel economy beyond the boiler room—a field that has been allowed to go down hill.

Boiler rooms must meet the demand made upon them, but that demand is created outside of their confines, and engineers who desire to measure up to present day standards must do everything possible to make that demand as reasonable as possible.

A few random recommendations to obtain this result may be summarized as follows:

Many unnecessary lights are kept burning. Get everybody to help the cause by turning them off.

Your belts are not looked after closely enough. You are losing power and money by having belts too tight or too loose.

Your motors are underloaded. Loss in efficiency and power is large if motors run much under load.

Your shafting should be lined up. Friction load in the average plant is very high, and power is wasted at a terrific rate if shafting is out of line.

You have a lot of uncovered high-pressure steam pipes. Your losses are high from this cause.

You have many machines running idle and wasting power. Install belt hooks and slip the belts off on machine shutdown for long periods. If for short periods educate the operators to shift to loose pulley.

Fix your doors and windows in cold weather to prevent undue loss of heat.

Wash your windows. You have an opportunity many days in the year to save at least half an hour of lighting by doing so.

Your fire-room practice should be improved. Keep fires bright, fire frequently, avoid holes, clean regularly, keep ashpit cleaned out, clean tubes oftener, get better damper regulation.

Many other suggestions of the common sense variety could of course be made but it is evident that if engineers work concertedly to attain this end an economy in fuel must, of necessity, result.

Simply Penny Wise

THE use of obsolete methods of generating steam is an example of the old adage, "Penny wise and pound foolish," yet it is practised in many plants in Canada to-day, with the idea of saving money.

Where coal is used as a fuel, it is too often dumped in a pile several hundred feet from the boiler house to be hauled to the firemen on either wheelbarrows or carts. This results in three successive handlings, each necessitating a certain amount of waste as well as requiring the retention of manual labor on the job simply to perform this work.

The installation of a railroad switch to a storage bin or yard, from which the coal could be discharged by means of a hopper or similar device to hand lorries running on a track in front of the boilers for hand firing; or to an automatic distribution system, if stokers are in use, it must be admitted involves considerable initial expense, dependent of course on the size of the plant, but the saving in fuel waste and useless labor will pay for this first cost in two years' time under average conditions.

Deliver the Goods

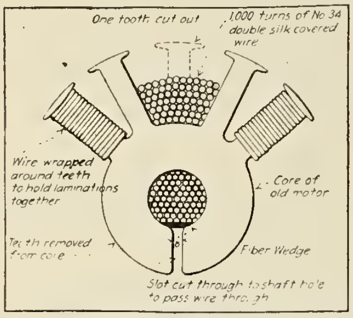
TO INVEST money for "refinements" without a reasonable certainty that greater efficiency and a lower operating expense will result is far from the purpose of the real engineer of to-day. A keen sense of analysis, good judgment and extensive practical experience are vital qualifications if a man is to "deliver the goods," retain the confidence of his employer and cut his operating expense and fixed charges. No change should be made, however slight, unless cash is available to carry it through as planned, and it is beyond doubt that greater economy will result from new equipment or methods.

Practical Ideas From Practical Men

SHORT CIRCUIT TESTS

Any engineer seeking a simple test to locate grounds and short circuits in small stators may find the following outfit, which we made in our shop, valuable for use on 110 volts, 60 cycles:

We moved the shaft from an old d. c. fan motor armature and cut off the teeth as shown in the accompanying sketch. A slot was then cut in one side to allow the wires of the winding to be inserted in the hole formerly occupied by the shaft. A thousand turns of No. 34 double-silk-covered wire were wound on. After the winding was put in, wedges were inserted to hold it in place. Lamp-cord leads were fastened to the growler and taped.



One tooth cut out
1,000 turns of No 34 double silk covered wire
Wire wrapped around teeth to hold laminations together
Core of old motor
Teeth removed from core
Fiber Wedge
Slot cut through to shaft hole to pass wire through

Details of construction of small growler.

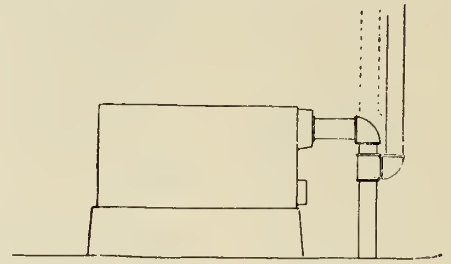
To test for shorts, this small growler is placed on the stator teeth and a tin feeler is used across the slots, one coil pitch in advance of the growler. If the tin vibrates there is a short in that slot. To test for grounds, place the growler on the core and then touch one lead of the stator winding to the iron core. If a spark is produced, the winding is grounded. This test can be made after a stator is rewound and before connecting it up. Try each coil in the starting and running winding. The slot the ground is in can be located by making a good steady contact with one lead of the grounded coil to the stator core; then apply the growler and use the tin feeler to bridge the slots until it vibrates.—A. C. Roe.

BOOSTING TEMPERATURES

In the local electric light plant they had a 1,000 h.p. feed water heater of the open or contact type which took steam from a 12-in. exhaust riser, the connection to the heater having been made from a tee, as outlined in broken lines on the illustration, the surplus steam passing up through the exhaust pipe to atmosphere.

While they had plenty of steam always available, they were unable to get a higher feed temperature than 195 deg. though sometimes under heavy load it fell below this. The engineer in charge had assumed that the apparatus was not large enough and had it in mind to secure a new and larger heater when funds were available.

While visiting the plant one day he called the heater matter to my attention, asking what I thought about it, and I recalled a similar experience I had been up against under almost similar conditions, and recommended that they make a change in the piping so that the exhaust steam would not have the chance to shoot right up the exhaust pipe without being forced into the heater. This was accomplished by the change in piping shown in solid lines from which it will be seen that the flow of steam to the heater has the preference at all times, and this change having been made, at the expense of two elbows, the temperature immediately went up to 212 and stayed there even under the peak load conditions.



J. C. N.

CEMENT WORK PAINT

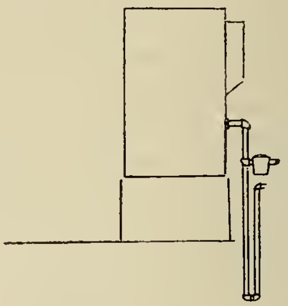
In a new addition which we put to our power plant we had a number of concrete piers and foundation structures which we wanted to paint in some way to keep them from dusting. A considerable area had to be covered and the use of an oil paint would have involved quite an expense, so we took advantage of the suggestion of a neighboring engineer that we use a coating which he had found satisfactory, made up of equal parts of cement and kerosene mixed together thoroughly, and then the addition of four or five parts of coal tar. This gave us a waterproof coating which was admirably adapted for the work we had in mind, at a low cost, and with good results as to durability.

S. T. M.

HEATER LEAKS OIL

In one of my former plants we had a direct contact feed heater which gave excellent service as far as water heating was concerned, but which occasionally got us on the anxious bench because it would allow oil to get through to the boilers. After a number of attempts at hunting down the trouble, we located it in the independent trap which was installed to take care of the overflow and oil drip.

The thick grease which came down from the separator would gradually accumulate in the trap until it clogged things up, causing it to work sluggishly until perhaps another slug of overflow water would come over and clear it out. We decided, therefore, to do away with the uncertainty involved in the operation of the trap, and since we were only carrying about 2½ pounds back pressure, we built a pipe water leg seal, making it about six feet deep. This we put into service and have never had occasion to be worried over oil in the boilers since.

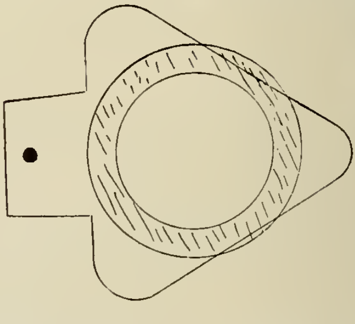


C. B. W.

INSTALLING GASKETS

Probably no job which the average engineer has to do is more detested than that of installing new gaskets, especially in old lines which are already installed, and where replacements usually have to be done after closing hour or in a big rush, with hot pipes, etc.

Where the pipes can be sprung sufficiently to permit easy inserting of the gasket the job is not so difficult, but where little "give" can be had, the job of sliding the gasket up between the flange faces is one that is a good test for patience.



Having had several jobs of that kind to do, and having found that a flat piece of tin helped materially in inserting the gaskets, the writer decided to add a "tool" of this nature to his kit, making it of thin sheet brass, of the form shown in the attached sketch, the purpose being to support and hold the gasket as it is being slid in between the flange faces, and to keep it from catching on the inner edge of the flange and buckling.

H. A. H.

WATER FEEDING METHOD

I wish to hear from some of the readers of your useful journal regarding what is recognized as the best method of feeding water into the water jacketed refuse burner as used at sawmills. I consider it should go in near the top and in descending pass the ascending heated water.

The one I am interested in is practically a vertical, hollow, cylindrical tank constructed of eight tiers of ⅜-in. plate, with a flanged bottom; it is 30 ft. internal dia., 33 ft. external dia. and 64 ft. high, thus forming a parallel water jacket 18 inches wide.

The grates are ranged around the inner circumference, the refuse is dumped through an opening 28 ft. from the bottom and considerable wood is disposed of in this 30 ft. dia. space in a working day.

There are three feed inlets to this tank: the two original ones 5 in. and 4 in. dia. each enter through the side about 8 inches from the bottom and is connected with an ell with a vertical length of pipe perforated along its entire length with ¾-in. holes; the other inlet, added later, is a 3-in. pipe entering about 24 ft. from the bottom and is connected with a short length of perforated pipe.

Two 5-in. pipes take the overflow from the top of this burner, one of which is connected with the boiler feed tank; and two 3-in. drain or blow-down pipes are attached to the bottom diametrically opposite each other.

We have considerable trouble at times in keeping the temperature of the water at the top of this burner below boiling point, when there is violent ebullition.

What I object to is that when pumping water through the 5-in. and 3-in. inlets to the limit of our capacity, the temperature of which may be about 45 deg., the temperature of the water at the top of the burner may be around 200 deg. while the temperature at the bottom will be around 60 deg. even though we are running considerable water through the bottom drains in an endeavor to lessen the disparity between the temperature of the water at the top and at the bottom of the burner.

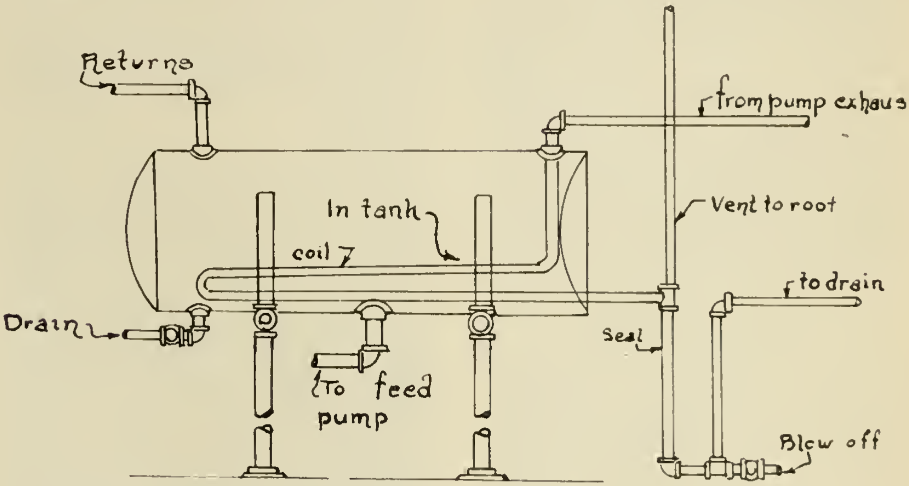
There has been considerable leakage at the seams of the three bottom tiers of plates and some distortion of these plates on the inside of the burner. I consider this trouble due, to a great extent, to the difference in temperature between the top and bottom of this tank: the plates will be practically the temperature of the water with which they are in contact: a difference of 100 deg. in temperature means a difference of ¾ in. in the length of the inner circumference of this burner, and even with a height of 64 ft. I reckon this will put a curious stress and strain on the material of the plates, as it adapts itself to this condition, and the greater the difference in temperature the greater the stress and the resulting strain.

Golden, B. C. O. E. S.

EXHAUST STEAM ENERGY

The use of exhaust steam from engines, turbines, pumps, compressors, and other steam propelled machinery, for heating purposes, has long since ceased to be a novelty.

Exhaust steam was used with varying degrees of success, for heating purposes, before the present day vacuum system came into use. However, as with other present day improvements in industry, defects in the early methods of using exhaust steam for heating, served as a stimulus to their solution.



Showing exhaust from pumps used in heater

It was an outstanding fact that there was a need of some method for removing back pressure on the engine to secure greater economy in power generation, which had much to do with the development of the vacuum heating system.

The old heating method, of using exhaust steam, consisted of discharging the exhaust into a none too well planned, piping system, and forcing it through the heating units against the resistance offered by air due to improper means for venting it, and the friction of pipes. This condition would cause a back pressure, some times, of as much as ten pounds, which materially cut down the efficiency of the engine.

Cut Back Pressure

To reduce this back pressure, several things were necessary:

(a) Improved piping installation, free of pockets, and well dripped to remove any accumulation of condensation.

(b) The application of vacuum traps at the return end of pipe coils and radiators, and steam main drips, so as to provide for the free and easy venting of air from all heating units.

(c) The installing of a definite common return piping system, well graded to avoid pockets, which would connect from the vacuum traps on all of the radiators, coils and steam main drip traps.

(d) This return main piping system would grade back to, and would carry all of the air and water of condensation from the heating system to a vacuum producing pump.

(e) The vacuum producing pump would draw all air and water of condensation away from the radiators, which would allow the steam, exhausting from the engine, to flow to the various heating units, with the minimum pressure to provide circulation.

The function of the vacuum trap, at the radiators and on the steam main drips, is to pass all air and water and to close off, preventing the loss of any steam into the return line piping system.

The vacuum system of heating, in connection with power plants, where exhaust steam is utilized, had gradually been refined until to-day circulation can be secured throughout a well designed system at practically atmospheric pressure, and oftentimes it is possible to produce an actual vacuum on the exhaust side of the engine, or other fixture furnishing the exhaust steam.

Exhaust steam contains about 85 per cent. of the original heat units after it leaves the engine, but, it also contains an amount of oil. It is obvious that this oil, if permitted to pass with the steam through the heating system, would cause a great deal of difficulty such as—reduced efficiency of heating surfaces, because of oil film on the inside—the gradual clogging up of piping, traps, etc.—but the greatest damage would occur through the returning of this oil, with condensation, back to the boiler.

Must Extract Oil

It is thus necessary to make use of the very best methods of extracting the oil from the exhaust steam, before making use of the exhaust in the heating system.

Some times, in addition to the oil separators, in the exhaust steam line, an oil filter is used to filter the condensation returning from the heating system.

One safeguard against oil, is the use of a heater with an oil separator attached to it, through which the exhaust steam passes. If care is always taken to keep the drain from such an oil separator thoroughly clean and in good working order, there will be comparatively little oil pass into the heating system, and as all of the heated water usually passes through a coke filter bed to the boiler feed pump, this process tends to further reduce the percentage of oil in the boiler feed water.

Boiler Pressure Varies

There are many boiler plant installations where this type of installation serves a group of buildings, situated a considerable distance from the boiler plant. The plant usually consists of more than one boiler, and is equipped with steam driven vacuum and boiler feed pumps. The boiler pressure may vary from forty to eighty pounds or more, and this pressure may be carried through smaller distributing mains a considerable distance to the respective buildings in the group, and at these individual buildings, reduced through reducing pressure valves, to the low pressure necessary for the heating system.

In this case, the amount of exhaust steam discharged from the pump at the boiler plant is not sufficient to warrant the use of a heater, yet it is desirable to make use of the exhaust steam from the pump in some manner, and it is apparent that it would be unprofitable to attempt to discharge the exhaust steam through an oil separator into a low pressure heating main, due to the fact that the low pressure heating mains are located too far away in the individual buildings.

Cuts Steam Waste

The illustration* shows a method of utilizing all, or a portion of this exhaust steam, by discharging the exhaust through a coil located in the tank. A large quantity of the heat is absorbed by the water before passing through the feed pump back to the boiler, and the oil and excess steam above that absorbed by the feed water is discharged through a convenient drain and vented out of the boiler room at some convenient point.

Sometimes a laundry room, or other small building adjacent to the boiler house, containing a few radiators may make use of this exhaust steam from the pump, and the condensation is then wasted to the drain.

---

*Illustration by C. A. Dunham Co., Toronto, Ont.

To reverse the direction of rotation of a compound-wound-motor either reverse the armature leads, keeping the other connection the same, or leave the armature leads untouched and reverse both the series and the shunt fields; or shift the brushes, as in the case of the shunt motor.

Convention Notes

Complete plans have now been made by the executive committee of the Montreal Spring meeting of the American Society of Mechanical Engineers, to be held at the Mount Royal Hotel from May 28 to 31.

On the opening night of the convention the council of the A. S. M. E. will be entertained to a dinner at the St. James Club by the council of The Engineering Institute of Canada. On the following evening the Montreal branch will tender a complimentary smoking concert at the Mount Royal Hotel to the delegates.

The committee in charge of the arrangements is composed of: H. H. Vaughan, chairman; J. A. Duchastel, vice-chairman; Fraser S. Keith, secretary, and Fred B. Brown, John T. Farmer, George R. McLeod, and Major C. M. McKergow.

The work of the convention itself will be largely of a technical nature. In addition to the general sessions on the opening day, there will be technical sessions on the following days devoted to the following subjects: Power, textiles, machine shop practice, management applied to the pulp and paper industry, port development, fuels, railroads and general mechanical engineering, with papers by experts in these lines from all over the continent.

A feature of the technical program will be the paper on Tuesday morning on hydro-electric development, by Julian C. Smith, vice-president and chief engineer of the Shawinigan Water and Power Company, who will speak on the power developments in the province of Quebec, and Fred Gaby, chief engineer of the Hydro-Electric Power Commission of Ontario, who will discuss the progress of that work.

The second session on power will have two papers, one by H. G. Acres, hydraulic engineer of the Hydro-Electric Power Commission of Ontario, on "Modern Hydro-Electric Turbines of Large Capacity," and Payne Dean, Stamford, Conn., on "Sectionalization of Remote Control of High Pressure Steam Lines."

C.A.S.E. Notes

Toronto No. 1 at its first meeting in May had a very large attendance. Whether it was the wiles of the typewriter of the secretary or the annual meeting for the nomination of officers, has yet to be found out but many were the congratulations offered Bro. John Brown who was looking remarkably well after his long illness.

Among others present were Bro. M. B. Watson, director of engineering at the Central Technical School; C. B. Turner, president of the Exhibitors' Association; J. Thompson, president of the Supply Men's Association, and H. Fletcher, director of sales for the Garlock Packing Co.

The officers elected for the coming year were:—

President, R. McLaren, by acclamation, because of his ability to bring in interesting papers on educational matters, mingled with ability to get new members.

Vice-president, Ed. Golightly, by ballot, because he is young and aspiring.

Corresponding secretary, Geo. A. Brown, by ballot, but modesty forbids me to say why.

Financial secretary, T. S. Jones, by ballot, because he is a first-class engineer and a little new blood on the executive helps to keep the best of organizations in trim.

Treasurer, Geo. J. Soucy, by acclamation, because he is an optimist and knows how to keep the bank account well filled.

Conductor, J. Quinlin, by acclamation, because he is polite and decorous and does things in such a nice way that one of the scrutineers said he deserved the freedom of the city of Toronto.

Doorkeeper, L. W. Thomas, by ballot because he ushers more in than out.

At the next meeting delegates to the convention will be elected.

Geo. A. Brown, Secretary.

At the last regular meeting in Kitchener we had Bro. Ellis with us and he gave an interesting talk on blackboard work on A. C. motors. We had a good attendance and everybody was well pleased with the lecture. We also initiated Bro. Wilson, chief engineer at the Kitchener and Waterloo Hospital.

At our next regular meeting on May 25th we will have a lecture on steam turbines.—C. Ott, Secretary.

London No. 30 C. A. S. E. held their regular meeting May 4th and the coming convention was freely discussed.

Officers for the coming year were elected as follows: President, Geo. Mott; vice-president, D. J. Freedy; rec. sec., G. F. Galloway; financial secretary and treasurer, Jos. H. Ward; conductor, J. W. Reynolds; door keeper, T. W. Baker; auditors, Freedy, Reynolds and Baker; delegate, J. H. Ward.

J. H. Ward, Secretary.

U.C.C. of E. Notes

On May 14 Canada Council No. 27 held a regular session, a good attendance and busy meeting. Delegates to represent us at the Rochester, N. Y., convention were elected as follows:

Delegates	Alternates
Chas. L. Holmes	L. Westwood
Jas. L. Cudbird	G. Aldridge
A. M. Aucterlonie	C. Shaw
H. E. Terry	H. Potter
Geo. H. Jenkins	W. A. Bruce
P. Davies	

The convention will be held Aug. 7.

Odd Questions and Their Answers

Queries are invited on the every-day problems of engineers in all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped a fellow engineer and a pleasure for us to pass on the data.

G. W. V. A. HEATING SYSTEM

The G. W. V. A. house at Welland is at present heated by a hot air system which is practically worn out and has cost considerable money for operation in the past winter.

Kindly give us advice on the proper heating system to install, remembering that economy in initial outlay is a great consideration.—P. A. W., Welland.

Answer:—In view of the size of the building and the general layout, that is with part of the building being used as a residence and the large assembly room on the first floor, some type of steam heating would be best. Since economy in initial outlay is the main consideration a one-pipe gravity system would be preferable. No excavation work is necessary as there is sufficient space in the basement.

A cast iron boiler of a reliable make, in which bituminous coal could be burned would assist in keeping down the fuel bill.

* * * *

SAFETY VALVE SIZES

What is the largest size safety valve allowed on an air compressor?—C. A. S. E.

Answer:—The safety valve of a compressor must be large enough to relieve the receiver of the full capacity of the compressor without any appreciable rise in pressure above that at which it opens.

There is a limit on the minimum but not on the maximum size which may be used.

* * * *

EFFECT OF COAL CHANGE

What do you consider the effect on efficiency of having the coal constantly changing, not only in ash and heat value, but in coming from different fields, particularly on hand-fired outfits where there are no instruments to aid the engineer in his work?—A. C.

Answer.—It is quite possible that constant changes in the grade of fuel used will result in destroying the regular operation of the boiler plant to such an extent as to have a definite effect on the economic performance of the plant.

If the boilers in the given plant are hand-fired, the firemen become accustomed to handling a certain type of coal and usually work out a more or less definite schedule as to how the coal should be handled, that is, whether the fuel should be fired fairly heavy, or light, or the fuel bed will or will not stand slicing, or whether it may or may not need breaking up with a hoe, etc.

With a given load on their boilers, the firemen usually have definite times for cleaning fires. Any material change in the character of the fuel being used will often times upset this schedule, and make a change in the period between cleanings and it may take a long time for the firemen to get accustomed to the fuel and establish a new schedule. If the coal is bought in fairly small quantities, these schedules may have to be worked out so frequently as to keep the operation of the boiler plant more or less upset right along.

In addition to the actual reduction in economy, due to the upset of one schedule and working out of another, resulting from changing the fuels in a given plant, there is also the psychological effect that such changes have on the firemen.

When fuel is supplied to a plant which gives little trouble in cleaning fires and keeping up steam, the firemen usually protest when a poorer grade of coal is furnished them, and in many cases become so indifferent to their work that the economy in the plant is greatly reduced. This condition often does lead to disputes and differences between the firemen and their employers which may result in the loss of good firemen and possibly the substitution of less experienced men.

* * * *

FUSE SIZES

How do you determine the ampere size fuses to use for a given h. p. motor?

Answer.—A. h. p. is 746 watts. Volts × amperes = watts. As the current flowing determines the size of fuse it is only necessary to know this and allow a suitable margin for starting current or temporary overload. In the case of a D. C. motor multiply the h. p. by 746 and divide by the voltage, to find the amperes. The A. C. motor is more complicated; power factor must be taken into account. For single phase multiply h. p. by 746 and divide by voltage and by power factor to find amperes. In polyphase motors the current flowing in each branch is

$$I = \frac{\text{H. P.} \times 746}{\sqrt{3} \times V \times \text{Power Factor} \times \text{Eff.}}$$

It is usual to add 25 per cent. to full load current to allow for overload.

* * * *

SETTING BOILERS

How much should a return tubular boiler be set lower at the back end than at the front end?—C. A. S. E.

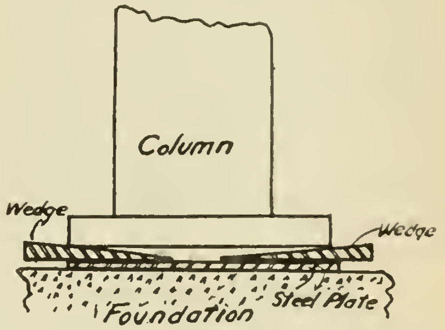
Answer.—Most manufacturers of return tubular boilers advise setting the back end from one to two inches lower than the front end, sufficient to allow good drainage to the back end.

* * * *

RAISING BOILERS

I wish to raise three horizontal return tubular boilers ½ inch. They are hung by cast iron columns and beams. Kindly give procedure.—W. W. P. Sinclair, Medicine Hat.

Answer:—Make a number of thin iron wedges and drive under the base of the columns as shown in the illustration. If the concrete has a tendency to crush under the wedges, chip away sufficient under one half of the column to insert a thin steel plate, then wedge between the plate and the base of the column.



By raising one end of each boiler at a time and blocking up with ½ in. steel plate, a small number of wedges will suffice for the three boilers.

* * * *

A TRANSMISSION PROBLEM

In our factory we are running at present from one of our 390 h. p. Allis-Chalmers heavy duty Corliss engines, one 100 kw. direct current generator. Our engine has one fly wheel on it 15 feet in diameter by 30 inches wide, speed of the engine 90 r. p. m.

We want to put a heavier load on this engine and by so doing we will then be able to shut off one of our other engines entirely and effect at least about a 10 per cent. saving in coal. We are somewhat limited for space in our power house and also considering a contemplated change at a further date regarding our power requirements; we do not want to purchase any larger generator equipment at this time.

It has, therefore, been suggested that instead of buying now a 200 kw. new generator to set in place of our present 100 kw. generator, that we leave this 100 kw. generator where it is, and connect to the same fly wheel of our engine another generator that we have on hand, thus running the two generators off the one fly wheel and having one leather belt running over the other.—A Reader.

Answer.—This scheme is perfectly feasible, just as the scheme of increasing the power of a drive by super-imposing another belt on the original belt. The second belt is referred to as a "rider" belt, and the applications of the idea may be found in many plants throughout Canada.

The fly wheel width of 30 inches is fully sufficient for a belt width to meet a load of 200 kw. It would be well for you to investigate the character of the surface of the fly wheel before proceeding with the installation. Iron casts rough and uneven and with warping and twisting of patterns, gives a surface that may not be entirely suitable for belt driving. Also in this connection the expense of dismounting the fly wheel and returning should be considered.

The load characteristics of your plant are a serious consideration in this type of drive. It is obvious that the use of the generator employing the under belt for an operation that is intermittent would mean either removing this belt or running that generator idle during the periods of non-use. In the latter case, this will mean the carrying of the mechanical losses of the generator, while in the former case the outside belt would be a very loose drive and may not be entirely satisfactory. That is to say, that with one particular direction of drive on the fly wheel, the surface of contact with the belt would be considerably reduced.

* * * *

FORCED-DRAFT FANS

Can you give me any instructions for operating forced-draft fans?

Answer.—Forced-draft fans should be started under minimum load by having the damper closed when starting. This also prevents the furnace gases from being forced out of the side doors if the stack damper is not properly set. The main oil switch should be used only for the purpose of disconnecting electrical energy from fans, and if it automatically trips, then something unusual has happened which requires the attention of an electrical mechanic before starting the fans again. The following instructions for starting and shutting down forced-draft fans have been taken from the operating code of a well known electrical company:

1. See that the forced-draft damper is closed.
2. Turn on the cooling water to the bearings.
3. Start the turbine or motor.
4. Inspect the oiling system and see that the gear case contains the proper quantity of oil and that oil rings, pumps, etc., are in operation.
5. Bring the unit up to speed.
6. Inspect the unit for excessive vibration, and if excessive vibration is discovered, report the trouble to the shift superintendent.
7. If the main oil switch (controlled at the boiler operating boards) should trip, have an inspection made by the electrical mechanic and any trouble corrected before closing time.

Shutting Down

1. Shut down the turbine or motor.
2. Turn off the cooling water.
3. Close the forced-draft damper.

* * * *

INCREASED HORSE POWER

In how many ways can the H. P. of a non-condensing engine be increased?—C. A. S. E.

Answer:—The general formula for H. P. is given by the following: P. L. A. N. where

P—Mean effective pressure.
L—Length of stroke.
A—Area of piston.
N—Revolutions per minute.

Assuming that no change can be made in the design of the engine and no condenser is to be added the only ways in which the H. P. may be increased, are by an increase in speed or by an increase in the M. E. P.

Speed.—The increase in H. P. is almost directly proportional to the increase in speed.

M. E. P.—This may be increased by an increase in boiler pressure or by altering the point of cut-off so that steam will follow up the piston for a greater length of the stroke. In the simple D slide, valve cut-off may be varied by changing both the angle of advance and the throw of the eccentric, the less the angular advance and the longer the throw the later the cut-off.

* * * *

COAL OR OIL

How can I determine when it is advisable to change from coal to oil burning, also, if I find it advisable to install one oil burning unit, which one of these systems would you advise and why?—gravity flow, low pressure head steam jet and high mechanical atomization?—C. A. S. E.

Answer:—When it is advisable to change from coal burning to oil burning depends on many factors apart from the relative cost of the fuels based solely on a B. t. u. basis.

Local conditions, such as storage room available, efficiency of coal and ash handling equipment, labor costs, smoke nuisance and boiler rating and efficiency desired, all must be taken into account. No general rule may be given, each installation needs to be studied in detail.

The system adopted also depends on local conditions, but where only one unit is to be installed it would be well to use a simple installation, possibly gravity flow. Steam atomizers use from 3 to 5 per cent. of the total steam produced. This would be objectionable in a heating plant where the condensate was repended on for boiler feed.

RADIATOR LOCATION

Is it possible to locate the radiators on the floor for the purposes of heating a one-storey building? The boiler is a return tubular, set about three feet above the floor and the radiators are at present located on the ceiling.—R. I., Winnipeg.

Answer:—Two possible methods may be applied to this change in installation, both necessitating the purchase of some additional equipment. The best method, applicable to any boiler pressure, is to install, beside the boiler, a small, motor-driven, centrifugal pump, fitted with automatic control. To this pump would be connected the returns from the floor radiators. When sufficient condensation water had collected in the pump control chamber, the automatic control would throw the switch, and the pump would force the water back into the boiler. If your radiation surface does not exceed 3,000 feet a motor of less than one horse-power will suffice. These are obtainable for operation from any type of current.

A second method is the installation of a couple of steam traps, one above the boiler and the other on the floor beside it. Connections would necessitate a steam supply from the boiler to each trap, the main return from the radiators to the floor trap, a return from the floor trap to the second trap, and a return from the second trap to the boiler. Such a system would necessitate maintaining a pressure of at least ten pounds on the boiler and might possibly give trouble if the fires were banked during the night.

As to comparative costs, the second system is somewhat cheaper than the installation of a pump, but we understand that there is some possibility of legislation being enacted by the Ontario government forbidding the installation of steam traps above boilers.

* * * *

STEAM ACTION

How does the steam act on the tube of a pressure gauge so as to make it straighten out and why is the longer axis of the tube sometimes at right angles to the spindle to which the pointer is attached?—J. M.

Answer:—The pressure of the steam in the boiler acts against the condensed water with which the so-called syphon tube is filled. This tube is necessary to prevent the hot steam from causing inaccurate readings on the gauge. Since the tube inside the gauge is coiled up, the outer surface has a greater area than the inner surface and therefore receives greater pressure, tending to make the tube uncoil. This action is communicated to the pointer of the gauge by means of a spindle. The variation of the relative positions of the tube and spindle are irrelevant and are due simply to different designs employed by manufacturers.

More modern practice in pressure and temperature gauges is to employ the recording type, in which the action of the coil is transmitted to a recording pen by means of two link arms, providing the recorder with a non-variable centre. Additional equipment in the recording type is a clock movement which rotates the dial face bearing specially ruled paper upon which the temperature or pressure is recorded.

* * * *

GENERATOR REWINDING

I have a small four-pole dynamo which I wish to rewind to supply about 20 amps. for the purpose of charging batteries. Would you advise such procedure?—W. R. T.

Answer:—It would seem that, for the purpose you mention, rewinding the generator would hardly be a sound proposition. In small units, nearly all storage batteries are charged by means of rectifiers operating on alternating current. If your operation is either large or small, suitable apparatus can be obtained to meet varying requirements. The rewinding of the generator would be a job for a firm specializing in such work, and while the cost would be considered less, provided the generator is in good condition, than the cost of installing a rectifier, the efficiency of the generator for battery charging would not compare with that of the rectifier. If it is a question of installing the proper equipment for the charging of batteries alone, we would advise a rectifier.

* * * *

PERCENTAGE OF CLEARANCE

Can you tell me why the percentage of clearance is greater in high-speed than in low-speed engines?—D. A.

Answer:—The term "high-speed" is commonly applied to shaft-governed single-valve engines of shorter stroke than slow-speed single-valve engines of the same bore of cylinder.

The long and large steam passages required in single-valve engines, together with the mechanical piston clearance, makes the actual clearance space as great as for a slow-speed, single-valve engine of the same diameter of cylinder, but having a shorter stroke, the cylinder clearance space becomes a larger percentage of the piston displacement.

In four-valve high-speed engines with non-releasing gear, the actual cylinder clearance volume may be as low as in an engine of the same diameter of cylinder and slower rotative speed, but as usually designed, the stroke is shorter in proportion to the diameter of the cylinder than in slower-speed releasing gear engines of the same diameter of cylinder and same piston speed; therefore the same actual clearance becomes a larger percentage of piston displacement, although less than in the single-valve engine of the same diameter and stroke, because the actual clearance is less.

* * * *

CALCULATING WIRE SIZES

Is there any method of calculating the size of wire for armature coils?

Answer:—Where an electrical machine is to operate on one-half the voltage that it was originally designed for, the number of turns in the winding connected in series must be reduced by one-half. Since the number of turns is reduced by one-half, the cross-section of the conductors in each coil can be increased by two. On the other hand, if the voltage is reduced by 4 the number of turns in series must be reduced by 4 and the size of the copper can be increased by 4.

Conversely, if the voltage is increased by 2 the number of turns must be increased by 2 and the size of the copper reduced to one-half. This is easily figured out. But if the voltage is increased or decreased by, say, 25 per cent., the size of copper may not be so easily determined by those who do not have their arithmetic at their finger tips.

For example, take the case where the coils of a 120-volt armature are wound with 8 turns of No. 12 copper and it is desired to rewind the machine for 90 volts. The number of turns per coil will vary directly as the volts and is equal to,

$$\frac{\text{New volts} \times \text{Original turns}}{\text{Original volts}} = \frac{90 \times 12}{120}$$

= 9 turns. No. 12 copper has a cross-sectional area of 6,530 circ. mils, and since there are 12 turns in the original coil, there is 6,530 × 12 = 78,360 circ. mils cross-section in the coil conductors.

Now the new coil should have approximately the same cross-section of copper. Therefore if the original cross-sectional area of the coil in circular mils is divided by the new number of turns, the new size of wire will be obtained. In this problem 78,360 ÷ 9 = 8,703 circ. mils. The nearest standard size of wire to this is a No. 11, which has 8,234 circ. mils cross-sectional area.

From this it is seen that the one thing to remember is that the new turns in the coil must have approximately the same total cross-sectional area as the original turns.

* * * *

CAST-IRON PISTON RINGS

What is the usual turned diameter and thickness of cast-iron piston rings for steam pistons?

Answer:—The rule for piston rings when made of cast iron is to turn them out of the solid ¼ in. larger than the cylinder diameter for cylinders 20 in. in diameter, and then cut out enough to spring the ring to the diameter of the cylinder. For larger or smaller cylinders the greater diameter for turning the ring out of the solid and the amount to be cut out is in proportion. That is, a ring for a 15-in. cylinder would be turned off, solid 10 3/16 in. diameter and then have enough cut out to be sprung to the diameter of the cylinder.

The thickness is commonly made 1/30 of the cylinder diameter plus ⅛ in., and the width is made equal to the thickness plus ¼ in. Hence for a 15-in. cylinder the thickness would be 15/30 + ⅛ = ⅝. and the breadth would be ⅝ + ¼ = ⅞ in.

For an eccentric ring—that is, with the thickest part diametrically opposite to the cut ends—the average thickness is made the same as for a ring of uniform thickness and the thickness at the place where the ring is cut is made two-thirds of the greatest thickness. Thus, for a 15-in. cylinder the average thickness of an eccentric ring would be ⅝ in., the thickest part would be 1.2 × ⅝ = ¾ in.; the thickness at the cut ends would be 0.8 × ⅝ = ½ in.; and the width as for a ring of uniform thickness for the same diameter of cylinder would be ⅞ in.

* * * *

BLOWING DOWN BOILERS

When is the proper time to blow down a boiler when banked or when steaming at full blast?—C. A. S. E.

Answer:—The best time to blow down a boiler is after a period of rest, and with a small head of steam. A good time is in the morning when firing up for the day, before full pressure is raised, the sediment then has had time to settle.

* * * *

BOILER HORSEPOWER

Kindly state how to work out the horsepower of a boiler and give probable size of a boiler required to heat a building having 14,000 sq. ft. of radiation surface.—P. E. L., Winnipeg.

Answer:—Manufacturers of boilers usually rate their boilers on a basis of the number of square feet of heating surface they contain, generally allowing 10 sq. ft. of heating surface per boiler horsepower.

All the surface in contact with fire or hot gases on one side and water on the other is called heating surface, the area of the tube sheets, being small in comparison with the total, is neglected.

To illustrate the method of calculating heating surface, consider a horizontal return tubular boiler with a 42-inch shell 14 ft. long with 34 three-inch tubes:—

Circumference of shell—3.1416 × 42 = 11 ft.

Surface of shell—14 × 11 = 154 sq. ft.

Suppose brick work corbeled off so that full half of shell may be considered as heating surface.

Heating surface of shell—77 sq. ft.

Internal circumference of one tube —3.1416 × 2.782 = 8.74 inches.

Internal area of tube—14 × 12 × 8.74 = 1468.3 sq. in.

Internal area of 34 tubes—34 × 1468.3 = 49,922 sq. in. or 346 sq. ft.

Total heating surface—77 + 346.6 = 423.6 sq. ft.

Allowing 10 sq. ft. of heating surface per boiler horsepower gives 42.3 H. P.

For the average factory with 14,000 sq. ft. of radiation surface a 150 H. P. boiler should be used.

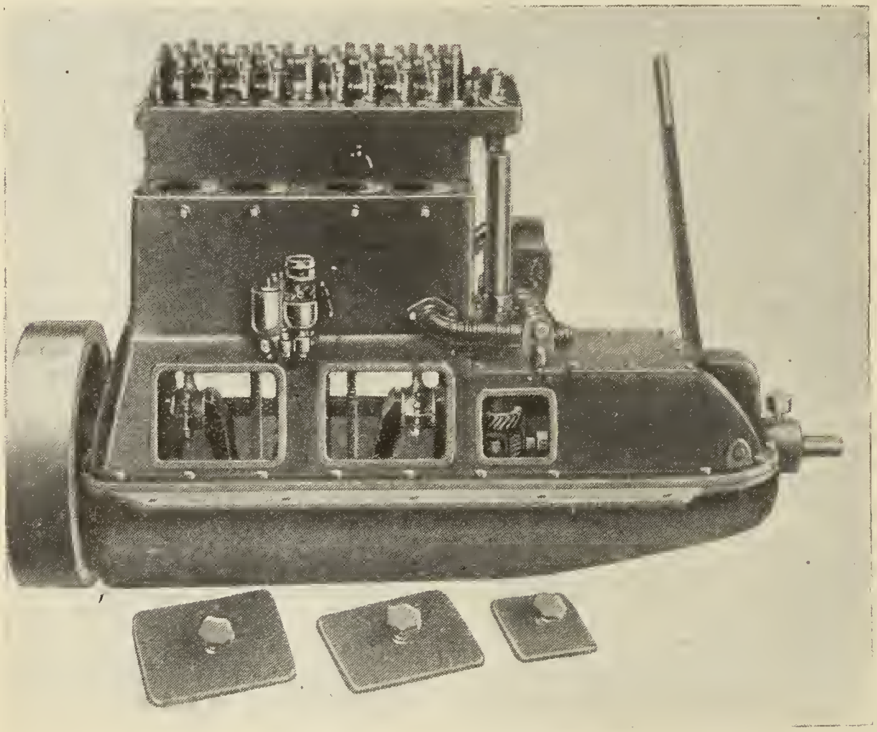
Fuses are rated at their maximum continuous current-carrying capacities and will usually blow at current values about 25 per cent. above their rating, depending upon the duration of the load.

Progress in New Power Equipment

New Engine Design

The Simplex Motor and Machine Co., 48 Abell St., Toronto, are putting on the market shortly an engine which embodies several revolutionary ideas in design. The striking feature of the new engine is the absence of springs on the valve stems, which are completely mechanically driven, a principle which, it is claimed, does away with all valve noises in addition to increasing the ease of adjustment in operation. Other variations from the ordinary type of engine are, a unique system of lubrication, provision for double installation of spark plugs and the removal of all gases from the engine through the exhaust.

The engine is of particularly clean-cut appearance, being of the completely enclosed type. While, from the illustration it would appear somewhat higher than ordinary, the vertical dimensions correspond with those of similar marine or automobile engines. The stroke and bore of the engine are 3½ x 5 and on rough tests it has developed over 20 h. p. The overall weight, with marine transmission is 620 lbs.



New Simplex Motor.

Mounted on the top of the cylinder head and driven by a vertical shaft as illustrated, the cam shaft carries a double set of cams for each valve stem. The tappets are mounted on a hollow shaft, which serves as an oil conveyor, slightly above the cam shaft. The end of each valve stem is fitted with a removable washer and the tappets are so designed that one engages the top of this washer while the other fits tightly under it. By properly mounting the cams and tappets to operate at the correct time, it will be seen that the valve will be opened and closed mechanically by the action of the tappets on both sides of the disc on the valve stems. A feature of this arrangement is the fact that all tappets are instantly adjustable on the tappet shaft by means of a set screw and lock nut on each. The manufacturers maintain that the new principle will completely obviate all noise and other valve troubles, in addition to providing greater accessibility in valve grinding and adjustment.

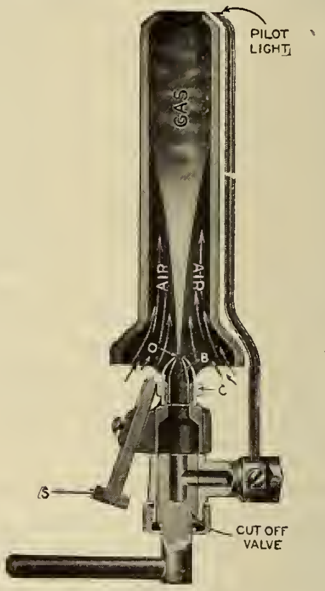
The oil of the lubrication system passes up from the crank case through a vertical tube at the front of the engine and supplies the cams and tappets, the former operating in oil continually. From the top of the cylinders the oil returns to the crank case through the casing of the vertical cam shaft drive.

An engine of this type has been operated for one season by the inventor, E. S. Lorimer, in a 28 foot motor boat and in this hull, which was not designed for speed in any way, he obtained 18 miles an hour. In a proper hull, it is claimed, that the new engine, operating at approximately 1,400 r. p. m. will develop over 20 miles per hour.

Production on an extensive scale is to begin very shortly.

Direct Jet Regulator

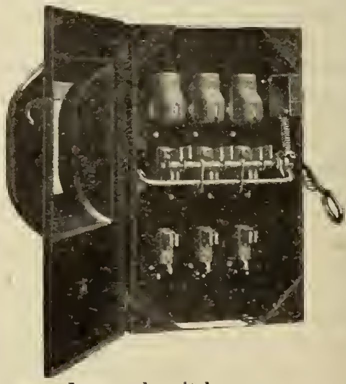
The device here illustrated is used in connection with the atmospheric bunsen burners, and can be used in service with any type of gas burner other than those used for blast purposes. The regulating feature permits of an adjustable gas orifice, and one that delivers a solid jet of gas directly down the centre of the mixing tube under maximum jet velocity, producing perfect combustion, and results in giving a high flame temperature without the use of any forced air blast or blower. These regulators are made by the Johnson Gas Appliance Co., Ceda' Rapids, Iowa.



Direct Jet Regulator

Safety Switch Cover

It is now claimed that the safety switch has been perfected to the point where it is just about 100% safe. The last point of danger to be removed is the live line terminals and jaws which were exposed when the switch cover was open. This has been overcome by en-



Improved switch cover.

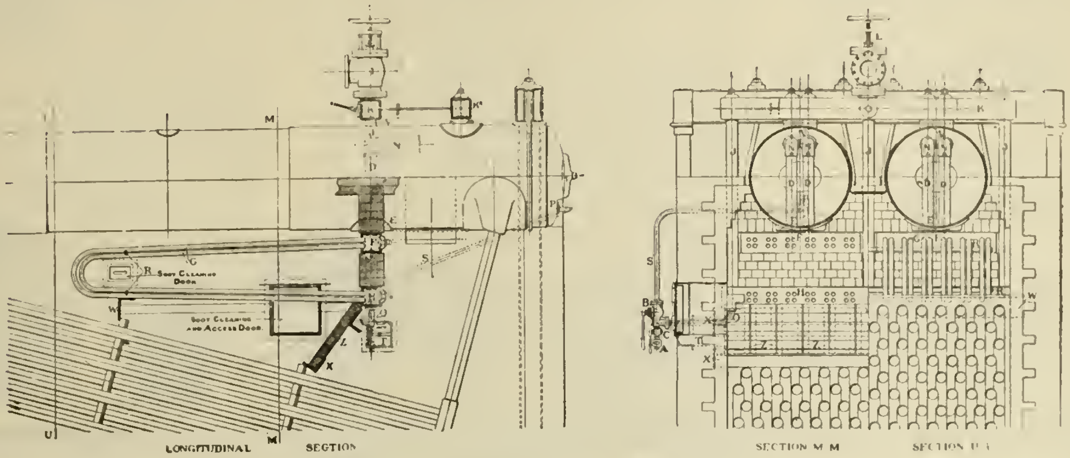
(Continued on page 42)

Babcock & Wilcox

Patent STEAM SUPERHEATER

(Integral with Boiler) (Standard Type)

Effects Great Economy in Fuel Consumption



Babcock & Wilcox Boiler Fitted With Integral Superheater.

DESCRIPTION

The Babcock and Wilcox Patent Integral Superheater has a heating surface consisting of solid drawn weldless steel tubes U shaped. These tubes are expanded and bellmouthed at both ends into holes drilled into wrought steel boxes (F) and (H).

The steam enters the upper box (F) through the dry pipes (N) and inlet pipes (D). It then passes through the superheater tubes (G) to the lower box (H), from this it ascends through the pipe (J) to the cross box (K) and the stop valve (L).

Hand holes are placed in the boxes opposite the ends of the superheater tubes.

There is also an arrangement for flooding the superheater with water from the boiler drum when starting the fires to prevent overheating of the tubes when there is no steam in them and for emptying this water from them at time of starting to steam.

This Superheater adds heating surface in a very effective part of your boiler and shows better efficiency by the lower temperature of the exit gases.

Your losses by radiation will not be so great and you avoid trouble with water in your steam pipes.

Superheaters are considered an absolute necessity by turbine users. Reciprocating engine users can save ten to twenty per cent. by the addition of enough superheat to make up for the heat robbed by the cylinder walls.

BABCOCK & WILCOX, LIMITED

TORONTO OFFICE:
Bank of Hamilton Building

ST. HENRY, MONTREAL

SAFETY SWITCH COVER

(Continued from page 40)

closing each live terminal and jaw in a protective cover. This box completely covers the terminal and jaw. Contact is obtained through a narrow slot just large enough to admit the switch blade, but too small for a finger to slip through. In addition to the protection from accidentally touching live terminals, the new porcelain covers protect the switch itself from all possibility of arcs. They can be attached or removed easily and quickly by means of two small spring clips, which hold the porcelain covers securely in place. They can be applied either before or after the switch has been installed. This feature, together with the individual base construction and key cover control, makes the modern safety switch practically 100 per cent. safe. These covers are made by the Square D Co., Detroit, Mich.

Construction

Orillia, Ont., plans the construction of a municipal heating plant, including boilers and equipment to use soft coal.

Sarnia Cement Products Co., Point Edward, Ont., is rebuilding its one-storey plant and plans to install three dry kilns, cupola, and one 20 h. p. electric motor.

Insurance Exchange Corp., Ltd., Montreal, Que., awarded the contract for the construction of a 10-storey office building on St. James St., to the Anglin, Norcross Co., Victoria St. Estimated cost $1,100,000.

Gowans Kent Ltd., 16 Front St. E., Toronto, plan the construction of an 8-storey factory for manufacturing purposes, including steam heating system and freight and passenger electric elevators. The cost is estimated at $300,000.

Western Quebec Power Company are planning to extend the power and distributing systems. Present capacity of 3,000 h. p. is likely to be increased to 6,000 h.p. before the end of the summer. If the work is carried through it will require additional capital, and a bond issue of $1,000,000 is being discussed.

Montreal has been authorized by the Legislature to spend $1,500,000 on the construction of a new City Hall. By using the old walls they will be able to keep within this sum. $200,000 already has been expended, mostly for the erection of the steel frame of the building.

East Kootenay Power Company, Cranbrook, British Columbia, announce that a contract has been let for the driving of a tunnel and other work in connection with installing a big hydro-electric plant on the Kootenay River, near Elko. It will cost $250,000 when completed.

The Canadian National Railways are building new railway yards at Kitchener. An extra gang of 26 men have started work, and this will be one of the biggest improvements that will take place on the central division this year. It is expected that the men will be engaged in this work during the greater part of the summer.

Dominion Government will erect its own building for the British Empire Exhibition to be held in London, England, next year. It will cost $1,000,000.

St. Maurice Power Co., Ltd., are proceeding actively on the new power project at La Sabelle, Quebec. The completed project will mean an additional 120,000 h.p. for the Shawinigan Power Company.

Ratepayers of Vernon, B. C., have recently authorized the city council to borrow $30,000 to establish a pumping station in the city park, and to carry out certain repairs required for the maintenance of the civic water system.

A sixteen-room structure to be known as the St. Pierre Claver School is to be erected at the corner of St. Joseph Boulevard and Delorimier Avenue, Montreal. Bernier and Despatie are the architects and work will be started sometime in June. It is expected the building will be ready for occupancy on Feb. 1, 1924.

Board of Trade and members of the Quebec harbour commission are discussing the construction of a cold storage plant in the port of Quebec which will cost $5,000,000. The Federal Government, it is expected, will make a loan of $5,000,000 for the construction of the plant, and the City of Quebec and the Provincial Government will furnish $26,000 between them every year for five years.

Power Notes

Toronto Gear Co., 175 Bathurst street Toronto, wish to procure a gear-cutting machine.

J. H. Lavin, Hillcrest Dairy, Whitby, Ont., is in the market for a 10 h. p. boiler and a steam turbine bottle washer and sterilizer.

A 150 B. H. P. Polar Diesel Engine is being installed by Lammers & Maase, Limited, Montreal, at the Blue Quartz Gold Mines Limited, Matheson, Ont., to drive the main air compressor.

A steam plant has up to now been used for the purpose, but the lower operating cost claimed for the Diesel engine has induced the management to make the change.

The Devoe Electric Switch Company of Montreal and Toronto have just been awarded the contract for the lighting safety panels and switchboards for the new big building which Henry Morgan & Co. Ltd., are adding to their Montreal store.

These panels are built on one solid base of "Bakelite" and will total in value to upwards of $20,000 exclusive of installation costs.

Taylor Stoker Company Limited, of Montreal, have just closed a contract for four automatic underfeed stokers with steam power dumps, fans and drive for same, to be installed under B. & W. Boilers in the plant of Bathurst Company Ltd., Bathurst, N. B.

These Taylor automatic underfeed stokers were made in Canada.

The John Inglis Co., Strachan Ave., Toronto, are this month delivering 3 pumping units to the city of Toronto. One of these is to be used in pumping the domestic water supply at Toronto Island, another is to be used in connection with the main sewerage equipment in the city, and the third is to be installed for the sewerage disposal system at Sunnyside.

G. D. Peters & Co. Ltd., of Montreal, who have recently introduced into Canada the well-known "Wilson Color-tipt" welding rods for electric arc welding, state that there is a growing demand for this product. Recent tests by the Canadian National Railway show that electric welds having a tensile strength as high as 67,000 pounds per square inch are now being obtained.

The City of Toronto is being pressed more closely as each month passes, by the need of certain public utilities. It is practically certain that on Jan. 1 next the ratepayers will be called upon to vote upon a duplicate waterworks system which will cost about $14,000,000. Another project which must be carried out very shortly is the installation of a $12,000,000 sewage disposal plant for North Toronto. In 1912 plans were submitted which called for a sewage disposal plant estimated at $6,000,000. The proposal was rejected and now the city will have to pay at least double for practically a similar installation.

Personals

A. J. T. Taylor, president Combustion Engineering Corporation, Toronto, has returned from a ten-day business trip in Eastern Canada, where the Corporation's operations are now centralized in the Canada Cement Co.'s building, Phillips Square, Montreal.

F. G. Morley, who has acted as secretary-treasurer for the Ontario Associated Boards of Trade and Chambers of Commerce since organization, has resigned his position, and Thomas Marshall, traffic manager of the Toronto Board of Trade, has been appointed his successor.

Toronto Hydro-Electric Commission will make an extension to its sub-station on Bay Street, which is estimated to cost about $90,000.

A shunt-wound machine when running as a motor will run in the same direction as when driven as a dynamo provided the connections remain unchanged. A series-wound machine when operated as a motor, will run in the opposite direction to that in which it must be driven to operate as a dynamo.

Dunham Packless Radiator Valve with 3 interchangeable parts

Simply constructed and uncommonly accessible! The Dunham Packless Radiator Valve is a sturdy, dependable and durable valve.

No springs or stuffing boxes. A remarkable "built up" bellows makes this valve absolutely leak proof. It can be fully opened or closed with approximately one turn of the vulcanized, non-breakable, heat resisting wheel handle. It's equally efficient for top or bottom radiator connection on steam or hot water type radiators where low pressure steam heating is used.

TYPE NO. 140.
Leakage of air into the radiators of vacuum systems is absolutely prevented by the "built-up" bellows construction. Steam, water, or dirt cannot come in contact with the valve spindle threads. Usable in any steam heating system.

MADE IN CANADA

Plant owners, executives and engineers are invited to write for the Dunham Hand Book which interestingly describes Dunham Heating Service and the application of Dunham Heating Specialties.

Toronto, Ontario
Halifax, Vancouver, Winnipeg, Ottawa, Montreal, Calgary.
London, Eng.: 18 St. Thomas St., S.E. 1.

The DUNHAM
REG. TRADE-MARK
HEATING SERVICE

ECONOMICAL DRIVE OF POWER

(Continued from page 30)

powers would be lower because of the lower vacuum. Ejectors may, of course, be installed instead of the air pumps.

The boiler-feed arrangements are the same in all the schemes, each boiler house containing one electrically-driven feed-pump, and one steam-driven (turbo) feed-pump, either of which is capable of supplying the whole boiler house, and both are always available for immediate use. In addition, the feed systems of the individual boiler houses would be interconnected, so that practically any feed-pump would be available for any boiler in case of emergency.

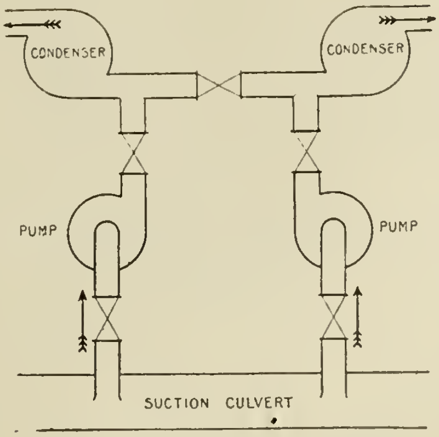
Six motors are provided for the stokers of each boiler house, but only three, each of 10 h.p., are required at any one time, the other three being available for immediate use by the operation of clutches.

Where a.c. motors are shown it is intended that, as previously mentioned, regulation should be obtained:

(a) For stokers, by variable gears.
(b) For pumps, by valves.
(c) For fans, by dampers.

For the reasons already given, feed heating by steam bled from the main turbines has been assumed in all the schemes, and the interlinking of feed heating with the use of steam from auxiliaries has not been considered.

In drawing up the alternative schemes the authors have endeavoured to keep to a minimum the number of oil switches on the main busbars, because every switch on the main bars must obviously be capable of breaking the whole capacity of the section of the busbars to which it is connected.



Synchronous motor-generators have only been put forward where it is necessary to provide for feeding the a.c. bars from the d.c. bars.

In all other cases induction motors are proposed because they are much less likely to trip out at times of fault on the a.c. supply, and they can also be started much more readily.

Fan for 2 Boilers

One forced-draught fan supplies two boilers and as a slight modification of the arrangements shown in the figures, it is well worth considering the advisability of feeding the induced-draught fan motors of each pair of boilers from one supply, and feeding the forced-draught fan motor of the same pair of boilers from the other, so that a failure of either auxiliary supply will not deprive any of the boilers of all artificial draught at times of peak load when both forced and induced draught are in use.

Where supplies to an auxiliary busbar are in parallel, it is to be understood that suitable reverse-current relays would be included to prevent other supplies feeding-in to any generator that may become faulty.

Layout in Fig. 1

D. C. generators would be self-excited, and reverse-current relays would be required between them and the d.c. busbar to prevent any possibility of motoring. They are not intended to supply current for the excitation of the main alternators, this being obtained from the usual type of exciter mounted on the main shaft, or from separately driven exciters if this latter method is preferred.

In many respects this scheme is similar to Scheme 4, but, as the possibility of total failure of auxiliaries is less, the size of the battery may be considerably reduced. The maintenance required would be fairly great because of the large number of d.c. motors, and a considerable number of spares would have to be carried, as both a.c. and d.c. motors are employed. However, there is much to commend the scheme if the d.c. generator can be considered a reliable proposition.

To rectify any minor trouble occurring with any d.c. generator without shutting down the main turbo-alternator, the troublesome generator would be switched off the bar, the d.c. supply being maintained by the other generators, which would each carry a larger load than usual, the battery and motor-generator assisting if necessary.

Layout in Fig. 2

Two auxiliary a.c. busbars, each fed by transformer.

An interconnecting switch is provided between the two 400-volt a.c. busbars, so that in the event of either transformer being out of action all the a.c. motors could be fed from the other transformer.

In view of the fact that, with the arrangements shown in Fig. 2, it would be necessary to start the first turbine of a "dead" station to atmosphere, as the station does not form one of an interconnector system (or even in the event of there being an interconnector, if this is out of action), it would be highly desirable to have at least one of the motor-generators of the synchronous type, so as to be reversible, thus dispensing with reverse-current relays on the d.c. side, and have the battery of sufficient output to carry the load of one set of turbine auxiliaries.

General Features of Scheme

This arrangement is simple in operation, efficient, and does not require a considerable amount of maintenance, and the spares required would be a minimum.

Where continuity of supply is very important, it is questionable as to whether this scheme can be considered to be really satisfactory.

The following arrangement of house set may be considered as being especially suitable for this scheme, and may increase the reliability of the auxiliary supply.

The house set to be of the simplest possible character, exhausting to atmosphere, and to be connected up so that the pressing of a button on the switchboard would enable the set to be on the bars within, say, 10/15 seconds. This would be effected by having a motor-operated steam stop-valve, the pipe line being so designed as to be continually drained. The lubrication arrangements would require special consideration.

As soon as the set approached full speed the governor would automatically put the generator on the busbars through a reactance, and one or two seconds later would short-circuit the reactance. The mechanical shock due to this switching would be severe, but the set would be designed to withstand it. By this means, in the event of the switchboard attendant observing a failure of supply on one of the auxiliary bars, he could run up the house set and switch off the faulty supply, with a reasonable chance of saving the motors on that auxiliary bar from being shut down.

Layout in Fig. 3

Special a.c. generator on shaft on main turbo-alternator, for turbine auxiliary motors only.

As stated in the table, for starting up from a "dead" station it would be necessary in this scheme to run to atmosphere the first turbine to be put on load, but if, before starting, the auxiliary generator were switched on to the motor which it normally feeds, these motors would run up to speed with the generator, and it appears possible that a vacuum might be obtained sufficiently quickly to avoid any distortion troubles in the main turbine.

In the event of a fault on one of the auxiliary generators, half the auxiliary motors of the main turbine to which it belongs will be shut down until the generator has been repaired or other arrangements have been made. To obviate this, switches might be installed so that the auxiliaries normally fed from the special generators could, in emergency, be fed from the auxiliary busbar.

In preparing the scheme the authors considered the use of such switches, but as with this arrangement there would be considerable danger of coupling together supplies which are not synchronized, and as the break-down of the auxiliary generators should be a very remote contingency, it was decided to omit them from the diagram.

Find Slight Difference

It will be noted, in comparing this with Scheme 2, that there is a slight difference between methods of connecting the low-tension sides of the auxiliary transformers to the busbar, but neither arrangement appears to have any special advantage over the other. The arrangement is simple in operation, efficient and does not require a very considerable amount of maintenance, and the spares would be at a minimum. The special a.c. generator should be more satisfactory in use than the d.c. generator of Schemel, and continuity of supply could be relied on to a considerable extent.

Layout in Fig. 4

Two auxiliary busbars, fed respectively by transformer and motor-generator.

This arrangement would be reliable, simple in operation, flexible and fairly efficient. It would require a fair amount of maintenance, because of the large number of d.c. motors used, and the spares required for the motors would be considerable. As a large battery would be required, the first cost of the scheme would be high.

In considering the relative merits of the foregoing scheme, it must be kept in mind that they are only typical and that it might be advantageous to adopt a combination of some of the alternatives. For instance, where all the supply, except the stoker motors, is shown as a.c. these also might be a.c. although the authors consider that this would be a rather unwise change. The ring main shown for the auxiliary (400-volt) busbar in Scheme 4 might equally well be adopted in any other of the arrangements. Instead of the d.c. generators of Scheme 1 feeding in parallel to one bar, they might each feed a separate bar, with an emergency switch to a common-battery bar, so that the battery might, as found necessary, be used for any group of auxiliaries.

Final Decision Difficult

It is also very difficult to come to a decision as to which is the best of the schemes, but on broad lines the authors suggest that they might be graded in two groups, the first and the best group containing Schemes 1 and 4. In the second group would be Schemes 2 and 3 which, although of equal merit one with another, cannot be considered as being of the standard of the first group.

Once the general scheme of the auxiliaries has been determined, a number of details having a considerable effect on the satisfactory running of the station must be considered.

The switch-gear and accessories used for the auxiliary gear of the station should be of the very best quality and design, for it would be unwise to run the risk of breakdown through false economy on plant, the cost of which is only a very small proportion of the total cost of the station. Switch-gear for electrical auxiliaries needs careful selection, especially with regard to the protective devices, in order that faults may cause the minimum shut-down, but at the same time to ensure that the protective gear will not operate except in case of faults.

Get Same Voltage

Where there are a.c. and d.c. low-voltage circuits in a station, these should be chosen so as both to give the same voltage on lighting circuits. For instance, in the schemes put forward, 400 volts a. c. give 230 volts between one phase and neutral, corresponding to the d.c. voltage of 230.

Considering the choice between the d.c. voltages of 230 and 460 the lower voltage would require only half the number of cells in the batteries, and, although these cells would be larger than in the case of the higher voltage, the reduction in the total number of cells would mean that less would be required in the boxes, and this would to some extent compensate for the extra copper required in the connections.

In all cases where a battery is not installed for d.c. auxiliaries, a small one would be put in for control circuits, and pilot lights fed from this should be placed at various points in the station, so that any failure in the main lighting supply will not result in total darkness in the station. Two motor-generators, one running and one as a stand-by, should be provided for this control battery.

Auxiliary Switchboard

As the drivers should be concerned solely with the starting of motors, the auxiliary supplies should be handled by a special auxiliary switchboard attendant. The auxiliary switchboard should not be far from the main high-tension control board; the high tension switchboard attendant would thus not be concerned with the details of the auxiliaries in the case of breakdown. Auxiliary

CLASSIFIED ADVERTISEMENTS

POSITION WANTED

FACTORY SUPERINTENDENT OR CHIEF Engineer is open for engagement. Have had wide experience in operating power plants and handling help in Canada. Apply Box 107, Power House.

FOR SALE

BOILERS FOR SALE CHEAP—TWO 100 horsepower, 110 pound steam. Apply Box 102 Power House.

BURNHAM STEAM PRESSURE PUMP, 10 IN. x 1¼-inch. x 12 in., nearly new, with Fisher governor attached. W. Ahearn, 538 McLaren St., Ottawa. When answering this advertisement please mention this paper. P.F.H.

FOR SALE—ONE 10 H.P. STEAM BOILER with base and 20 ft. smokestack; new flues and in A1 condition; also 1 steam turbine bottle washer and sterilizer; both in excellent working order. Apply Box, 103 Power House.

INDUCTION MOTOR — 220 VOLTS — 1800 r.p.m. 15 h.p.; single phase; can be bought cheap; write for particulars. Box 104, Power House.

I. H.C. 12 H.P. GAS ENGINE FOR SALE—ALL in good running shape, with 33-inch clutch pulley; will be sold reasonable on easy terms. Apply W. Harrison & Son, R. R. No. 5, Guelph. When answering this advertisement, please mention this paper. P.F.H.

SAWMILL MACHINERY—MODERN DESIGN—most satisfactory to operate. Apply Box 105, Power House.

SAWMILLS—PORTABLE — DOUBLE EDGES; also all kinds sawmill machinery. Apply Box 106, Power House.

TAYLOR SAFES FOR SALE—RARE OPPORTUNITY to secure a safe at small cost. They are in splendid condition. Inside dimensions and prices are as follows: 15" deep, 2 ft. 6" wide, 3 ft. 11½" high, fitted with built-in compartment. Price $250.00. 18" deep, 2 ft. 8" wide, 4 ft. 5" high, fitted with steel compartment. Price $200.00. Apply Box 10, POWER HOUSE.

WELDING

ELECTRIC AND ACETYLENE WELDING of broken castings and machine parts, boilers, tanks, and marine repairs. Carter Welding Co., Ltd., 165 Adelaide West, Toronto. Adelaide 2841.

BELTING BARGAIN

ABSOLUTE BELTING BARGAINS—BELTING every description; rubber hose, thresher supplies, tank pumps, pump leather feeds, canvas, McGill auto powers, special reduced prices; for quality and price, you can't beat us. N. Smith, 134 Adelaide west, corner of York, Toronto. When answering this advertisement, please mention this paper. P.F.H.

THE COMPASS OF INDUSTRY

5323

switchboards controlling duplicate supplies should be symmetrical and as close together as possible. Whenever possible all the feeders and cables duplicating the supply to any auxiliary should be run by different routes, so that in case of fire or mechanical damage the danger of the supply being cut off from all the auxiliaries would be reduced to a minimum. For example, in the case of the auxiliaries shown in Schemes 2 and 3, the feeders for the stoker motors should be led by different routes. As the motors may have to run without stoppage for periods of several weeks, special care must be taken in the design of starters, control gear, etc., to reduce to a minimum the heating due to resistance losses in conductors or to hysteresis in the ironwork.

The latter feature requires special attention, as apparatus which has been quite suitable for ordinary industrial service has become so hot when used on auxiliary plant for long periods without a break that it has had to be replaced. Contractor gear for starting has been adopted in certain cases, but the authors are of the opinion that there is little to justify the extra cost of this, although push-button releases operated from suitably chosen places in the station may be of considerable advantage. For example, a conveyor should have push-button releases provided at intervals along its length, so that the motor can be stopped at once in the event of breakage.

Starters for motors should be placed in very accessible positions and in sight of the moving machinery which they operate.

The use of motors, in addition to hand gear, for the operation of large valves such as those on main circulating pipes, is increasing. When these motors are d.c. it is to be noted that they must not be series wound, as a series motor may, once the valve gear is in motion, speed up to such an extent that considerable damage results.

A. c. slip-ring motors, where used for station auxiliaries, should be fitted with brush-lifting gear, and interlocks should be provided between this, the main oil switch and the rotor resistance, so that the main oil switch cannot be closed unless the short-circuiting gear and the rotor resistance are in their correct starting positions.

Batteries must in all cases be installed with hand-reversible boosters so as to be suitable for charging and discharging, and the protective gear should be such that in the event of a heavy overload the booster is cut out and the battery connected directly to the bars. End-cell regulation is unsuitable for station auxiliary work, as it entails taking the battery off the bars during charging.

Trade Catalogs

Stephens Chemical & Mfg. Co., of 2004 Dundas St. W., Toronto, have issued a pamphlet giving some surprising figures as to the effects of boiler scale on the efficiency of boiler operation. The company is marketing a product for the treatment of scale, the methods of application of which are outlined in the pamphlet, which is called "Efficiency."

The Main Electric Co., of Cleveland, makers of small complete lighting equipment, storage batteries, and battery charging apparatus, have just issued a booklet dealing with their products. Specifications are given very completely of each article, while a new departure is the inclusion of a description of radiophone sets, manufactured by the company.

The National Meter Co., 299 Broadway, New York, are issuing an attractive pamphlet dealing with the measurement of the flow of fuel oil by their "Empire" meter. In addition to an excellent illustration of the "Leviathan," one of the largest trans-Atlantic liners, on which National equipment is installed, the booklet contains a brief description of the operation of the meter illustrated by comprehensive diagrams.

The Dayton Safety Ladder Co. through their agents, Allen General Supplies, Ltd., 205 Yonge St., Toronto, have introduced to the market a ladder of a design both unique and pleasing. This ladder embodies many new features which are described in detail in their recent booklet which shows the application of the new equipment both in the factory and in the home. The pamphlet should prove of general interest.

G. F. Sterne & Sons, of Brantford, are the publishers of a series of booklets which should be of great interest to all who are interested in the operation of boilers. The most comprehensive of these books is entitled "Boiler Scale, Its Prevention and Removal," and deals with the elimination of this boiler room nuisance by the use of silicate of soda. The passage of water through a boiler is dealt with most thoroughly, attention being paid to all of the factors which enter the field. Attractively put together, this book should prove of value to all stationary engineers.

Other publications, recently issued by the same company, deal with the use of high temperature cements and fireclay for fireboxes, mountings, baffles, etc. In addition to their own manufacturing processes, the company are agents for several English and American firms producing articles of interest to the engineer.

The Combustion Control Co., of Philadelphia, have developed a special type of dual valve controller for maintaining an even rate of combustion in industrial furnaces. This apparatus, which is described with clear illustrations in their Bulletin No. 8-A, may be utilized to control temperature, pressure, or both. An interesting feature of the bulletin is the diagram of pressure charts, taken from recording meters, which shows the uniform results accomplished by the combustion controller.

The Lebanon Boiler Works (J. K. Petty & Co., Inc.), Philadelphia, Pa., strike a popular note in their recent booklet dealing with their Uniflow boilers. The matter is presented largely by illustrations and by tabulated statistics which contain much information of value to the operating engineer. In the Uniflow boiler, the efficiency of circulation is insured, it is claimed, by a novel mean of tube arrangements. This arrangement, together with other specialties, is completely set forth in the booklet.

"Maple Leaf"
Brand
Stitched Cotton Duck Belting *and* Dressing

It is water-proof and economical; also more efficient than other belting. The standard of quality, "Maple Leaf" Brand, is always maintained. That is why the demand for this belting is steadily increasing. "Maple Leaf" Brand Belting and Dressing make a good combination—use both.
Write for prices and further information.

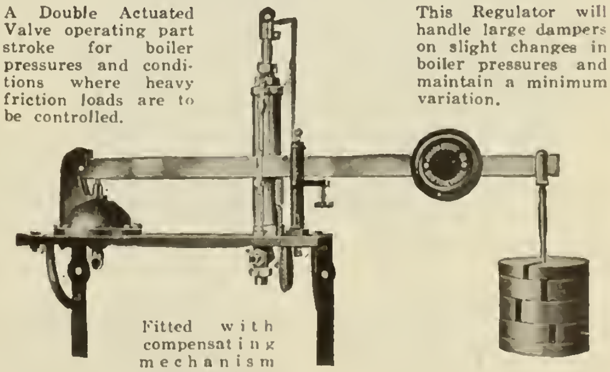
D'ESTE
Hydraulic Damper Regulator
A Double Actuated Valve operating part stroke for boiler pressures and conditions where heavy friction loads are to be controlled.
This Regulator will handle large dampers on slight changes in boiler pressures and maintain a minimum variation.



Fitted with compensating mechanism which regulates opening and closing.
Our Catalogue No. 50 of CURTIS ENGINEERING SPECIALTIES sent on application.

85% Magnesia

"Featherweight"

MAGNESIA
KEASBEY & MATTISON CO.
FEATHER WEIGHT
85%
AMBLER, PA.
SECTIONAL COVERINGS

Retains its
Coal-Saving
Qualities

It Never
Deteriorates

DON'T be misled! Many pipe coverings made in the past few years show up well under efficiency tests but in practice fail to stand up. Durable qualities are lacking. Cases are on record where such coverings have been shaken to pieces within a year.

You need pipe and boiler covering that holds its heat-conserving qualities for years. That is the only kind that pays. You want **K. & M. "Featherweight" 85% Magnesia Pipe and Boiler Covering.**

The same heat saving efficiency, the same saving of coal is registered, whether 85% Magnesia coverings have been on steam pipes for a week, a month, a year or a quarter of a century.

Let us explain more fully 85% Magnesia.

The Physician
considers each patient separately

He doesn't give every one a pill out of the same box. Scientific training and practical experience have taught him that each case must be studied individually, for best results.

In the same way, the wise power plant engineer wants boiler feed water regulation that is exactly suited to the conditions of his plant. That's why he specifies the

COPES System of Boiler Feed Water Regulation

Every COPES is exactly fitted to the special service for which it is intended. In every case the type of boiler, size of feed lines, normal and maximum ratings, steam pressure, method of firing, and pump control are taken into account when the regulator is designed.

The COPES is succeeding every day on the hardest kinds of service—for instance rolling mills, waste heat boilers, dye houses, cement mills, paper mills, and flash type vertical boilers. We have been able to meet every difficult boiler-feed situation successfully, by carefully fitting the regulator to its work, in each case.

Our method of doing this—and the results obtained—are interestingly described in Catalog "D." A copy will be sent gladly upon request.

NORTHERN EQUIPMENT CO., 112 West 11th St., Erie, Pa.
BRANCH PLANTS: Hamilton, Ontario, Canada; Croydon, England; Paris, France; Cologne, Germany.

COPES
SYSTEM OF BOILER FEED CONTROL

The Basis of most Boiler compounds, often sold under special names, is nothing but Silicate of Soda.

It is a fact that straight Silicate of Soda, properly graded, will positively remove and prevent all boiler scale.

"Boiler Brand" is sold for what it is—just one of our many grades of Silicate of Soda. You'll find its action similar to the most expensive compound.

Keep Your Boilers Efficient

with

BOILER BRAND

Silicate of Soda

No condition of boiler scale has yet been found that "Boiler Brand" will not handle if used in proper quantities. It stops pitting and corrosion by neutralizing the corrosive acids in the water. It protects and lengthens the life of packings and fittings.

Why Individual Boiler Feed Water Treatment

Because the Condition of Each Individual Boiler Differs

We have demonstrated it to be the most successful method of freeing boilers of scale and stopping the further formation of scale-forming deposits or incrustations. Corrosion or pitting stopped at once by our scientific process which accomplishes the results desired.

"CLEAN ALL"

Indicates in a few words what the process does.

Foxboro record of pressure in a Jefferson Vomiting Kier at the Lincoln Bleachery, Lonsdale, R. I.

FOXBORO

Helical Tube Movement

The unretouched photographs reproduced above show a Foxboro Helical Tube taken from stock. Note the uniformity of every convolution — striking proof of the superiority of the Foxboro method of drawing in the temper.

Foxboro Helical Tubes do not fatigue, split or leak. They are permanent in calibration and may be used constantly at maximum range without affecting their accuracy or strength.

The wonderful dependability of these tubes means much to users of Foxboro Recording Gauges, Thermometers and Psychrometers.

Up and Down 16,000 Times a Month!

What more exacting test could be made of the strength and elasticity of the Foxboro Helical Tube Movement than recording the pressure changes in this type of Bleaching Kier? Pressure in the kier is regulated by automatic controlling devices which raise and lower the pressure once every two minutes. The Foxboro chart record shown above was taken from one of several Foxboro Recording Gauges installed on Jefferson Vomiting Kiers at the Lincoln Bleachery, Lonsdale, R.I.

Up and down, 16,000 times a month, the pen arms of these gauges have accurately recorded the pressure changes for many months.

These gauges are identical in construction with the thousands of Foxboro Recorders that are performing less spectacular but no less dependable service in power plants the world over. Every Foxboro Recorder is built and tested to be fully worthy of its responsibility as "The Compass of Industry," no matter how severe the service it is called upon to give.

THE FILES STOKER

Pays for Itself in One Year

Below is a copy of one of the many letters we have received, telling of the efficiency and economy of the Files Hand-Operated Stoker

The Waterous Engine Works,
Brantford, Canada.

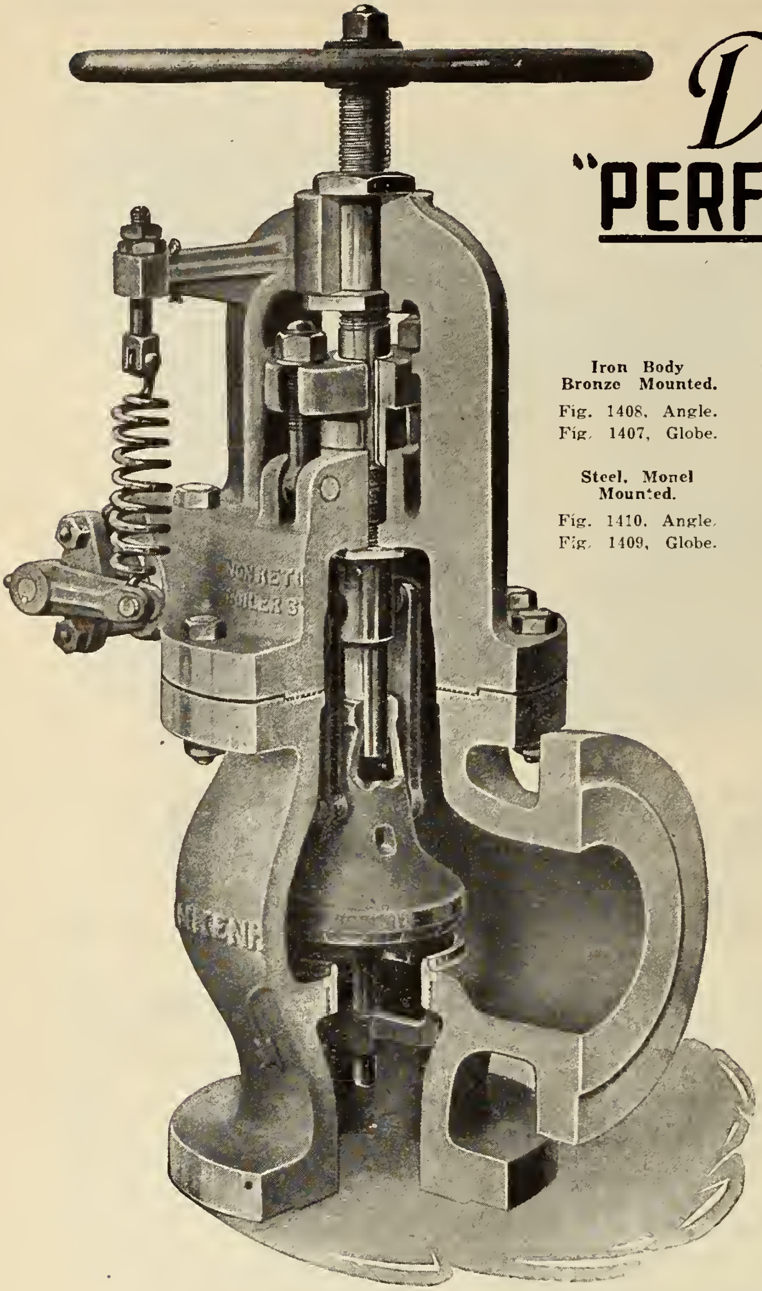
Gentlemen:

Replying to your recent letter. About a year ago we were using seven 150 H.P. Erie City Boilers, and were burning "Jellico" straight run of mine coal and could hardly keep up steam with it. In our coal preparation we get a fine screening known as "Bug Dust" and formerly threw this away, but recently we completed the raising of our boilers and the installation of Files Stokers, with the result that we never use over four boilers and burn the "Bug Dust" exclusively, and our power production cost is less than half of what it was formerly.

Waterous

BRANTFORD, ONTARIO, CANADA

Definition of a "PERFECT" Non-Return Valve



Iron Body Bronze Mounted.
Fig. 1408, Angle.
Fig. 1407, Globe.

Steel, Monel Mounted.
Fig. 1410, Angle.
Fig. 1409, Globe.

ONE that automatically and RELIABLY closes upon the sudden decrease of pressure in a boiler connected in battery to which it is attached and opens only when the pressure in the boiler equalizes with that in the header; that prevents steam from other boilers in battery escaping through a disabled one, thereby enabling the safe and uninterrupted operation of the plant through the medium of the live boilers; one in which the disc freely operates, does not stick and has external regulating means, conveniently and quickly adjustable, to eliminate chattering of the disc; one that facilitates assembling and disassembling for inspection, regrinding of seating surface, cleansing, or for renewing any part; and one that has a large factor of safety, offers the maximum service and economy of maintenance.

A better and shorter definition is

LUNKENHEIMER Safety Non-Return Valves

made in all standard sizes, Iron Body Bronze Mounted for 250 pounds pressure and 450° F. total temperature, or Steel, Monel Mounted for 350 pounds pressure and 800° F. total temperature.

Booklet 525 D.C. describes these Valves in detail. Write for a copy.

IN ENGINEERING CIRCLES

It is the operating engineer who most appreciates reliability.

Hours spent renewing rod packing and replacing gaskets, often in inaccessible places, have proved to him the fact that quality is the main consideration when purchasing packing. Added to this is the saving due to minimum rod friction and leakless joints.

On your next order specify GARLOCK, the packing of world-wide reputation and known reliability.

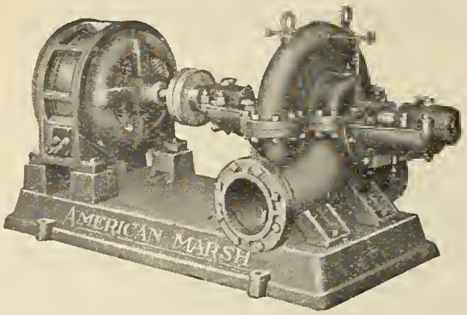
AMERICAN-MARSH PUMPS

Centrifugal and Direct Acting



Designed for use in power plants where absolute reliability and high efficiency are essential. For over thirty-five years American-Marsh Pumps have been recognized as standard throughout the Dominion. There are over 160,000 in successful operation.

The sturdy rugged construction and heavy cast bronze fittings insure long life and a minimum repair expense.

American-Marsh Centrifugal Pumps are built with the same painstaking care that characterizes the construction of the direct acting line.

The Line includes :

- Boiler Feed Pumps
- Air Compressors
- Deep Well Engines
- Centrifugal Pumps
- Jet Condensers
- Vacuum Pumps
- Condensation Pumps
- Sump Pumps

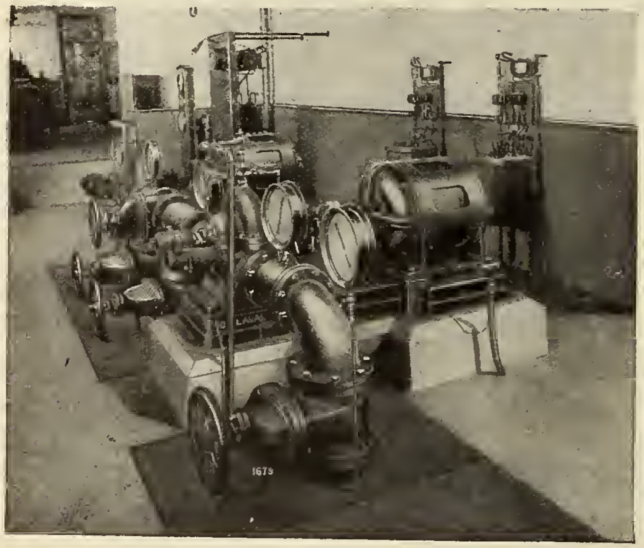
Collingwood Uses De Laval Motor Driven Pumps for Both Domestic and Fire Service



THE two De Laval motor driven pumps in the photograph were installed by the City of Collingwood, Ont., to provide both domestic and fire service. The pumps are each designed to deliver 1,200 gal. per min. against 165 ft. head at 1,740 r.p.m., but the piping is so arranged that the two pumps can be operated in series to give 330 ft. head.

De Laval centrifugal pumps are ideal for electric drive because of their high efficiencies and their power-limiting characteristics. The size of the motor can be selected to give the highest efficiency at the normal delivery of the pump, and the motor will not be overloaded even though the pump be allowed to discharge free against no head. This is also favorable to high power factor in induction motors, as is likewise the low starting torque required.

All De Laval pumps are guaranteed as to efficiency, capacity and power characteristics, and each unit is tested before it leaves the shops.

State your pumping requirements so that we may send specific information.

The
UNDER-FEED
STOKER
COMPANY
OF CANADA
LTD.

RILEY JONES MURPHY

It introduced a new era in underfeed stoker firing—

THE coming of the **"Lateral Retort"** Stoker brought a new epoch in stoker building—and a welcome one. It made available for every plant the high efficiency and high capacity of the multiple retort stoker at the installation and operating cost of the single retort stoker.

Although the **"Lateral Retort"** is multiple retort in effect, in construction it is a simple, single retort stoker. Coal, following the path of the arrows, is first underfed to the main retort and then, actuated by lateral pusher blocks, is underfed into the **"lateral retorts."** Finally, the ash is deposited upon easily operated side dump plates and is dropped into ash pits only 6 to 18 inches below the floor line—so shallow that no expensive ash pit construction is needed.

Ask for the **"Lateral Retort"** Bulletin that shows how this stoker is multiple retort in everything but price—how perfect coal distribution is obtained because of the control of the fuel bed afforded by the main ram and the auxiliary ram—how high efficiency is obtained because of the application of the underfeed principle—how heavy overload capacity is secured by great reserve capacity—how automatic control of fuel and air is given by the use of the Cole Automatic Valve—how features of construction give long life and freedom from excessive maintenance costs.

Your Copy of the Booklet awaits your postcard

Advantages of the *"Lateral Retort"* Principle

Coal is underfed throughout—not overfed on to side grates. This is the only truly *underfed* side-cleaning stoker.

One simple moving unit for five or more retorts—The feeding mechanism of the *"lateral retorts"* is controlled independently of main feed, permitting ideal fuel distribution under all conditions.

Simplest cleaning mechanism—a perfectly balanced dump plate easily operated by hand.

No need for basement ash pits—A trench 6 to 18 inches below the floor line is sufficient excavation for ash pits. This greatly reduces installation cost and makes the stoker adaptable to boilers already in service.

Plate tuyeres—reduce siftings and lower replacement cost.

High air cooled front and rear tuyere blocks keep fire and clinkers away from front wall and bridge wall, reducing furnace maintenance.

The "Lateral Retort" Stoker

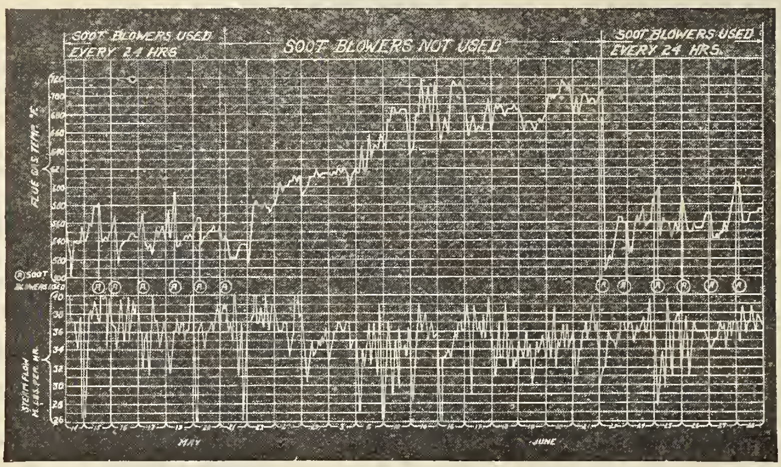
TRADE MARK

For Cheaper Steam Production Use Diamond Soot Blowers

The chart below covers the result of a test made by a public utility on a 780 H.P. vertical water tube boiler, 225 lbs. pressure, 130° superheat.

The soot blowers were used once a day for a period of eight days, after which the boiler was allowed to go without cleaning for thirty days.

It will be noted that as soon as operation of the soot blowers was discontinued, the temperature rose daily from an average of about 545° to about 680° at the end of the nineteenth day, after which it maintained this same average for the succeeding eleven days. When the blowers were again operated an immediate drop in temperature occurred from 680° to an average of 560° for the succeeding eight days. It will be seen that the load was fairly uniform throughout the test.



The extent to which Diamond soot blowers thus reduce the cost of steam production is obvious. The fuel saved by reducting the flue gas temperatures may be estimated at 1% for each 20° to 30° drop in flue gas temperature, depending upon the amount of excess air in the chimney gases.

On the basis of fuel saving, Diamond soot blowers are one of the best paying investments in the power plant. They pay for themselves many times over during their period of service.

Send data regarding your boiler equipment and write for full information. Ask for Bulletin 287.

Genuine British Oak Tanned LEATHER BELTING

Look for the Oak Leaf It's Your Guarantee

All hides used in the manufacture of D. K. McLaren's Belting are specially selected by men whose experience with hides guarantees the rejection of any that fail in any way to come up to the rigidly set McLaren Standard of quality.

In the manufacture of D. K. McLaren's Leather Belting, only the backs of the hides of the choicest steers are used. These are subjected to the Genuine British Oak Tanning Process which adds considerably to the original toughness of the hides and at the same time imparts a flexibility and a stretchless quality that is unequalled by any other process.

It is only after every inch of belting has been put to the severest tests that the Oak Leaf is stamped upon it as the D. K. McLaren Guarantee of efficiency, even under the most adverse conditions—your assurance of Belting with a grip that never slips.

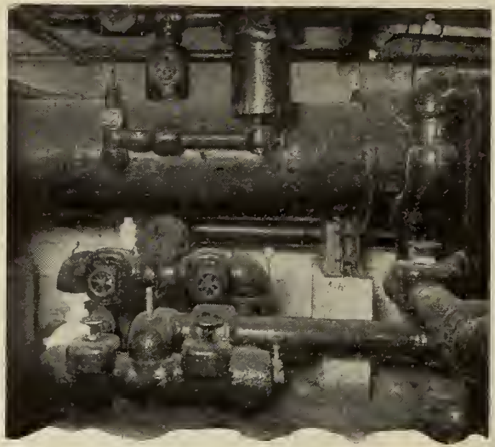
Walkerville Ontario



Illustrating the adaptability of Nonpareil Cork Covering to a great variety of equipment. Gatesworth Hotel, St. Louis, Mo.

These lines are *insulated*, not just covered

REFRIGERATED lines are not covered for appearances, or to protect the metal, or for any other purpose than to insulate them from the higher temperatures surrounding them. Though various materials are used to *cover* cold lines, mark this: Cork is the only material that will *insulate* them and continue to insulate them year after year without loss of efficiency. And certainly that is what you expect of your pipe covering—permanent insulation.

Nonpareil Cork Covering

For Brine and Ammonia Lines

is permanent insulation because it is moistureproof and frostproof. Being cellular in structure, not fibrous, Nonpareil Cork Covering has no capillary attraction for moisture. In addition, it is protected inside and outside by an impervious coating of mineral rubber. Properly applied and given reasonable attention, Nonpareil Cork Covering stays dry. Frost cannot get into it or under it.

Year after year, Nonpareil Cork Covering not only covers, but *insulates*, unchanged in structure, undiminished in efficiency and requiring no more maintenance than an annual inspection and painting.

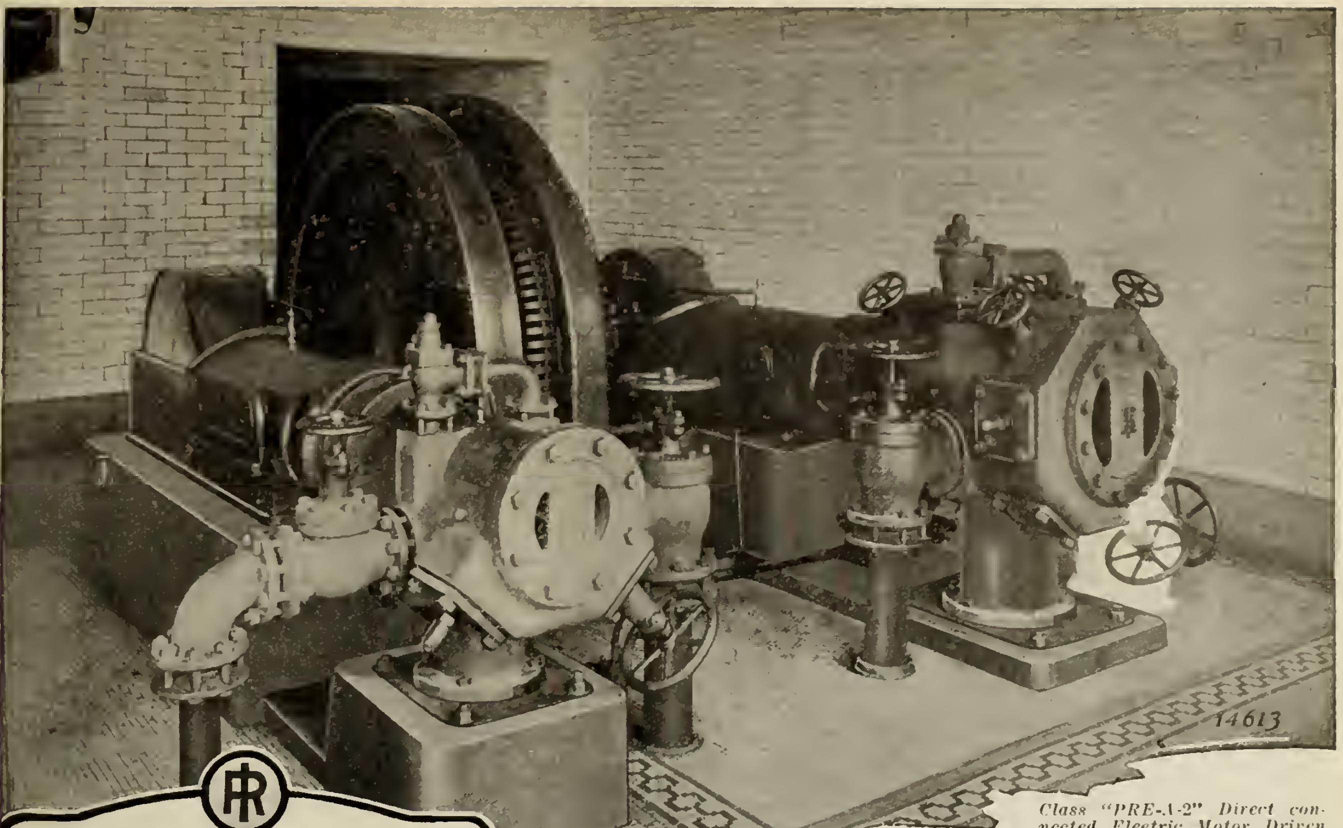
There is a Nonpareil Cork Covering for every temperature, for every pipe size and for every fitting.

◆

Write for the new 32-page book, "Permanent Covering for Refrigerated Lines and Tanks," just off the press. It is sent free on request, with a sample.

ARMSTRONG CORK & INSULATION COMPANY, LTD.

903 McGill Building, Montreal, Que.
11 Brant St., Toronto, Ontario, Can.



Class "PRE-A-2" Direct connected Electric Motor Driven Ammonia Compressor in one of the largest ice cream plants in the world.

Ice and Refrigeration Plant Equipment

Ammonia Compressors

Built for either single or two stage operation, and for belt, steam, oil engine or direct connected electrical motor drive.

Air Compressors

Can be furnished in all sizes and for any commercial discharge pressure. These units are particularly suitable for supplying air for agitation, air lift pumping or for general power purposes. Any type of drive.

Air Hoists

Built in five sizes for from 1,000 to 10,000 pounds capacity. These hoists are extensively used for lifting ice cans and for general hoisting work. They are easy to move about the plant, and simple to operate.

Pneumatic Tools

A complete line of riveters, drills, grinders, etc., for erection, assembly and repair work.

Cameron Pumps

For pumping brine, water and other liquids. These can be furnished in direct-acting type for steam or compressed air drive, or in centrifugal type for belt, motor, steam, oil or gas engine drive.

Price Oil Engines

Of the direct-injection, four-cycle type. Horizontal, single cylinder types of 50 and 100 H.P., and vertical, multi-cylinder types from 105 to 1,000 H.P. AC-3

Two-Stage Direct-Connected Electric Motor Driven Ammonia Compressors

Ingersoll-Rand Ammonia Compressors are ideally adapted to the needs of modern raw water ice manufacturers and cold storage plants.

Their two-stage compressing cylinders are fitted with I-R plate valves. Gas passages are unrestricted and valve areas are unusually large, guaranteeing maximum compression efficiency and consequently lower power cost per ton.

These compressors can be furnished with or without a water intercooler for cooling the ammonia gas between stages. This intercooler is of simple construction and easy to clean. Its use increases the efficiency of the system.

Clearance Pockets cast in the cylinder permit efficient unloading of the compressor to three-quarter or one-half capacity. Provision is made for completely unloading the machine during the starting period.

The Class PRE-A-2 Compressor shown above has the rotor of the synchronous motor, direct-connected to the compressor shaft. Ingersoll-Rand Ammonia Compressors are also furnished for belt, steam or direct-connected oil engine drive.

An Installation of Canadian Sirocco Induced Draft Apparatus

Individual Application of Equipment is the Vital Factor in Mechanical Draft

In the selection of mechanical draft apparatus, the proper selection of the blowing equipment to meet the individual demands of the plant it serves is second only to operating reliability. Control of capacity, pressure and speed, method of drive, economy of operation, etc., are a few of the factors that must be considered.

The wide use of Canadian Sirocco mechanical draft apparatus is due largely to the fact that there is Canadian Sirocco equipment of rugged design and maximum efficiency for every requirement. This, with definite and accurate knowledge of its performance, enables Canadian Sirocco Engineers to cooperate with you in the solution of any problem involved in mechanical draft installations.

Our engineers will be glad to submit recommendations covering your particular requirements.

Fisher Pressure Regulator.
(Type 90.)

A Money-Saver—WHY?

1. Because Fisher Pressure Regulator, Type 90, delivers to an operation or process exactly the amount of low pressure required—no more—no less. It maintains the desired low pressure without fluctuation, regardless of variations in high pressure.

2. When an operation or process is interrupted, this valve automatically cuts off the low pressure and remains closed until the demand at that point is renewed, when it automatically releases just the required low pressure.

Thousands are in use for curing, drying, bleaching, dyeing, vulcanizing, evaporating and similar processes in textile mills, cotton seed oil mills, sugar refineries, tobacco and rubber plants, lumber mills, etc.

Fisher Pressure Regulator, Type 90, saves enough to pay for itself in a very short time.

Send for Bulletin 210, which gives complete information about this wonderful valve.

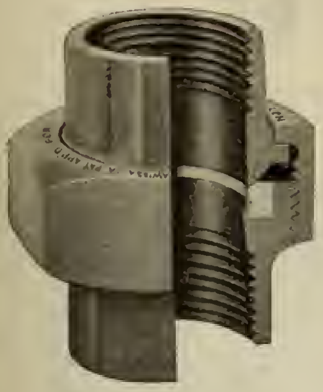
BRANTFORD :: CANADA

No More Union Trouble



Let us send you some interesting details of the "CATAWISSA."

THE "CATAWISSA" Forged Steel UNION is smaller and takes up less space, yet is stronger and will carry higher pressures than any other union.

All parts of the "CATAWISSA" are forged from refined steel bars, the forging process giving more than ordinary toughness and strength. Being made of the same material as the pipe to which it is attached, it expands and contracts WITH the pipe, preventing leaks. The forging process also renders it absolutely free from sand or blow holes which means that you lose no time in tearing down lines on account of union troubles. This union is made with ordinary Forged Steel, Brass or Monel Metal Seats, as desired.

MONEL METAL SEAT—The "wire-drawing" or cutting effect of the steam results in frequent leaks where ordinary unions are in use. The Monel Metal Seat of the "CATAWISSA" offsets both this and the danger of leaks from small cutting particles, besides being non-corrosive. It is the seat for high pressure temperature.

Every union is thoroughly tested under water with compressed air—the best known method.

POWER HOUSE

ESTABLISHED 1907 *Toronto, June 5th, 1923* A SEMI-MONTHLY NEWSPAPER

Burning Up Public Money As Boilers Explode!

By CAMPBELL BRADSHAW

Minister of Labor Rollo Too Busy These Days to Heed Charge of Canadian Engineers That "Holes" in Ontario Inspection Law Make it Poorest in Dominion

ENGINEERS fortunately, live and learn, unlike certain officials at Queen's Park who apparently live only to waste public money.

A "system" of government which champions the ridiculous and expensive division of authority in boiler inspection in Ontario, an anomaly which everyone admits has transformed a good law into the poorest legislation on the American continent, clearly shows how far public servants can shelve their avowed purpose of safeguarding life and property in order to retain their clutches on the spoils of "political war."

The inter-provincial boiler code has now been in operation since June, 1922, in the majority of the provinces of the Dominion, largely as the result of the splendid labor over a number of years of D. M. Medcalf, chief inspector of steam boilers for Ontario.

It has proven an excellent thing from the point of view of both the boiler manufacturer and the boiler purchaser, yet inspection remains the plaything of politics, to the amusement of all who know its value when made by properly qualified men.

From the point of view of the operating engineer, the more stringent the law the better, because adequate inspection safeguards his life, lessons his responsibility and protects the property under his care.

All Pleas Ignored

Boiler manufacturers, city officials, members of the Canadian Association of Stationary Engineers, of the Councils of the Universal Craftsmen, and of the International Union of Steam and Operating Engineers have time and again asked Minister of Labor Walter Rollo to amend the present law by bringing all inspection under one department, in order to reduce expense and promote efficiency. The only results have been "courteous promises of consideration" from J. H. H. Ballantyne, Deputy Minister of Labor; J. M. Brown, Chief Examiner of Engineers; and J. T. Burke, Chief Inspector of Factories.

And so the Steam Boiler Inspection Branch continues to supervise capably the construction of new boilers and the sale, exchange or extensive repairs of used boilers, while the Factory, Shop and Office Branch continues to flounder hopelessly on the inspection sands of boilers in operation, giving at least some credence to the proud boast of a few supporters of the government that efficient inspection of steam boilers is unnecessary, as Ontario is "immune from boiler explosions."

It is strange that even where representative government prevails, the interpretation of the time honored "serving the people" apparently reads differently in the case of the politician and the taxpayer. The official sometimes presumes upon his own size and sees himself as a wise and judicious censor although "ignorant" taxpayers had looked upon the man they salary as their responsible deputy. Deputy Minister of Labor Ballantyne refused to furnish Power House with photographs similar to those accompanying this article.

What political bunk! The records show that since the Boiler Act became effective in July, 1913, twenty-one explosions have resulted in a loss of twenty lives and serious injury to thirty-nine persons, in addition to a property loss of approximately half a million dollars. Yet everyone knows the explosion of a boiler is seldom an accident in the true sense of the word, because it usually proceeds from a cause which can be foreseen and the defects remedied.

Defects Easily Seen

A brief examination of the present law at once shows the "holes"—failure to place annual inspections under the proper department similarly to all other provinces in the Dominion, as well as Great Britain and the United States, and —a dearth in the Factory Branch of men qualified to make any power plant inspection.

Reference to the act, however, quickly shows that no reflection can be cast on any member of the department, as no engineering qualification whatever is necessary to serve as a factory inspector, Section 17 simply stating that "The Lieutenant-Governor in Council may appoint as many inspectors as may be deemed necessary, one of whom he may designate as chief inspector."

To demonstrate clearly the inconsistency of the existing law, take, for example, a boiler which has been constructed under the supervision of the Steam Boiler Branch, and a certificate of inspection issued. After a year has elapsed, the owner or operator of the boiler may carry any pressure he thinks fit or may alter the steam piping or any of the safety devices, and the Steam Boiler Branch has no authority to interfere in the matter.

"Scrap" Best Part

A little less than ten years ago the original act looked fine on paper, and met with the approval of boiler builders, boiler purchasers, stationary engineers and insurance companies. But alas, 'twas soon "scrapped," for shortly after its passage the government issued an order-in-council which nullified its most important feature.

This regulation of the Ontario cabinet placed on the Factory, Shop and Office Branch of the Department of Public

Works the responsibility of annually inspecting all boilers in the province, leaving to the inspectors, who possess the necessary qualifications and experience as a result of years of study in the construction, maintenance and operation of boilers, only the supervision of newly-constructed boilers, boilers which need extensive repairs, and second-hand boilers about to be sold. Further, these inspectors, according to the ruling, were adjudged incompetent to make inspections, although competent to specify the details of construction and test new boilers.

What an anomaly! When it is remembered that the regulations regarding new boilers are stringent in the extreme. Plans have to be submitted for approval, then after the parts have been inspected the boilers are given a hydrostatic test before being stamped with the amount of pressure to which they may be submitted.

This red tape ruling placing the inspection of operating boilers under the Factories, Shop and Office Branch of the government did not, however, make it incumbent upon these inspectors, many of whom are women, to crawl inside a boiler and see if any corrosion has taken place; to see if any of the plate has become so thin that a paper knife could be shoved through it, or to find a leak repaired by placing tar paper between two pieces of metal.

Oh no, factory inspectors do not make that kind of an inspection because they are not called upon to make it and could not if they were.

All they are required to do is to see that the "regulations" have been observed and that once in a while there hangs on the wall in the boiler room a certificate showing that the boiler has been inspected by a stationary engineer with license; even that, however, is not essential.

This Disaster Resulted in the Death of Two Men.

It must be noted that the order-in-council advanced the "original" idea of allowing any man with a stationary engineer's certificate, who has had charge of a stationary boiler and engine for a period of at least five years, to inspect any boiler—not, of course, his own boiler, but the boiler in the plant across the street.

Now, if Bill Jones across the street is a good friend of his, isn't it natural for him not to insist on letting the fire out, opening the back hand hole, or the manhole, to see if there is any scale inside?

Stands by Duty

Should the boiler subsequently explode, of course the owner cannot be censored because the legal "regulations" have been observed. The factory inspector has not failed in her duty, because when she last called everything was lovely, in fact, here and there a certificate was hanging on the wall in a nice little frame. Little solace to those, for example, who mourned the death of Clarence Edmonds, in the explosion on the Edmonds Farm in Houghton Township, or satisfaction to the jurors at Delhi who demanded, after investigating the tragedy, that adequate inspection of steam boilers must be provided in the province and must include those used for agricultural purposes.

Yet this boiler of 25 horse power, built 35 years ago, so far as is known had never been inspected since it left the factory.

It is needless to enumerate the many other catastrophes, such as the boiler explosion in a cheese factory at Joiceville, which resulted in the death of two men, or the tragedy at Howick Hall, in Ottawa, in which four were killed, twelve seriously injured, and the damage amounted to $100,000, all as the result of one defective valve.

It is no reflection on the ability of engineers in the province to say that 75 per cent. of them know little about boiler design and construction, although the majority are well able to remedy defects after they develop.

A man in charge of a boiler or an engine can operate them in a highly successful manner without possessing the qualifications necessary to make an intelligent inspection of a boiler under his care, to say nothing of the "competency" of the women whose inspection certainly must be defined under the Factories Inspection Act as legal.

May Screen Negligence

It might be well to point out that another reason why inspection by the friend of an operating engineer is undesirable, is because any damage existing in the plant is likely to be concealed with the object of screening negligence.

Buildings Demolished When Boiler Split in Twain.

Return Tubular Boiler After Explosion

The damage might be small but extremely dangerous, while on the other hand, of course, it might not be at all important.

There is, of course, no intention of disparaging the absolute capability of engineers in charge of large steam plants to inspect their own boilers, but as a matter of fact, of 87 stationary engineers interviewed, every engineer without exception declared flatly that he disapproved of any system of inspection which allowed a brother engineer to examine a boiler.

The consensus of opinion gathered from conversations with these men may be summed up in the statement that they believe the Act should be revised so as to bring not only the construction of all steam boilers including those used for agricultural purposes under the Steam Boiler Branch, but also that the same branch would be entirely responsible for the working pressures that boilers should be allowed to carry from time to time.

Finds System Wrong

J. E. Fitzgerald, of the T. Eaton Co., is emphatic in declaring that it is wrong for an engineer to inspect the boilers of a brother engineer, as it frequently happens in the smaller communities that the poorest operating engineer in the district does most of the inspecting. Mr. Fitzgerald suggests it might be possible for the chief boiler inspector to appoint a capable operating engineer to an inspectorship in isolated districts should emergency arise requiring his services.

Robert McLaren, of the Massey-Harris Co., firmly believes that all boiler inspection should be under the direct control of one man. He flatly disapproves of any method of inspection which allows the engineer of a nearby plant to inspect his friend's boiler. Mr. McLaren thinks such a regulation places engineers in an awkward position, as at times the ties of friendship might interfere with his best judgment.

Norman Smith, of the Brunswick-Balke Co., says that an inspector who is qualified to examine a steam boiler during construction is certainly capable of inspecting it while in operation. He also states that he has seen boilers in operation in Ontario which he would not consider at all safe. He thinks that the present system of grading licenses could be improved and that no operating engineer should be allowed to inspect any boiler.

Babcock and Wilcox Limited, pioneer manufacturers of water tube boilers, when asked for an expression of opinion, promptly replied:

"We certainly think that the inspection of boilers in operation should be directly under the jurisdiction of the Steam Boiler Branch, who have to pass on and inspect all new boilers. We believe in having one definite control in such matters."

E. Leonard & Sons, Limited, of London, Ontario, boiler manufacturers in business in the province since 1834, state quite frankly that the Act should be revised so as to bring, not only the construction of steam boilers under the Steam Boiler Branch, but also so that the annual inspection of steam boilers would be carried out by the Steam Boiler Branch in the same way as obtains in the Provinces of Alberta, Saskatchewan and British Columbia. In this way the Steam Boiler Branch could be made entirely responsible not only for the construction of a boiler, but also for the safe working pressures that they are allowed to carry from time to time.

Present System Dangerous

As one large factory owner puts it, the present system is worse than no inspection, since it makes everyone believe everything is all right and safe when it is all wrong and dangerous.

"The department, which is fully competent to guard human life, has had nothing to do with a boiler after it leaves the shop, indeed, does not see it at any time."

With regard to the charge heard in legislative halls that boilers are rapidly being replaced by hydro power, the records of new boilers constructed in Ontario in the past ten years is convincing proof that the boiler industry is not a declining one.

From July, 1913, to June, 1923, approximately 8,900 new boilers and pressure vessels were constructed, and of the 32,000 boilers at present in operation in the province, probably more than sixty per cent. are insured. A fortunate thing for the Drury government that so many owners of boilers, recognizing the loose form of government inspection, have insurance experts make capable inspections, otherwise the annual toll in human life might be incalculable.

Let those who defend the present system of boiler inspection remember that explosions in Ontario are more numerous than in any other province of the Dominion, despite the fact that the modern steam boiler as manufactured in Ontario, according to the best methods of design, if periodically inspected in a capable manner during operation, is perfectly safe.

Connecting rods are made larger at the crank end to overcome the resistance due to friction, which acts with a greater leverage on the crankpin than on the crosshead pin, the latter being smaller in diameter than the former. The stresses due to the inertia of the rod also call for a larger section of the rod at the crankpin end than at the crosshead pin.

The addition of lap will generally prevent the steam valve from opening sufficiently for the proper admission of steam, hence when the lap is increased it becomes necessary to increase the travel in order to provide the proper port opening. An increased travel of the valve also opens the port more rapidly, which is an important consideration.

A small storage battery may be charged from a 110 volt direct current circuit, by placing it in series-parallel with several incadescent lamps, the number depending on the charging rate of the battery. A 16-cp.. 110 volt carbon lamp will allow about half an ampere to flow through it. If the charging rate of the battery were 5 amperes, this would mean 10 lamps in parallel series with the battery. Be sure to connect the positive wire with the positive terminal of the battery.

Economies Result by Using Standard Feed Water

Impurities Cause Scale and Corrosion, Resulting in Excessive Heat Losses, Repair and Low Boiler Ratings, Despite All Efforts of the Engineer to Cut Costs

THE modern tendency in boiler plants to heat the feed water to above 200 deg. F. causes the lime and magnesia to separate and clog the heater and feed pipes.

The substances commonly found in feed water may be divided into six general classes, namely:

Suspended Matter:—Solids finely divided and held in suspension; mud, silt, silica, etc.

Temporary Hardness:—Chiefly soluble bicarbonate of calcium, magnesia and iron; which decomposes and precipitate on heating.

Permanent Hardness:—Any soluble substances which do not precipitate on heating, such as the sulphates, chlorides and nitrates of calcium, and magnesia. These have a tendency to react with the temporary hardness, concentration of these substances resulting in precipitation of calcium or magnesia, forming a very hard scale, or in some cases liberating corrosive acids.

Soluble Sodium and Potassium Salts:—These are permanently soluble and do not cause scale or corrosion.

Miscellaneous Soluble Substances:—Oxide of iron, alumina, silica and vegetable and mineral matter.

Evils of Impurities

Heater and feed pipes are clogged by precipitation of substances, causing temporary hardness. Scale in the boiler is largely due to temporary hardness.

Scale is also caused by permanent hardness, and in many cases accompanied by corrosion.

Acids cause excessive corrosion in feed pipes, heaters, boilers and steam lines.

Sodium and potassium salts tend to cause priming, especially if any oil or vegetable matter should happen to be in the boiler.

Scale, unfortunately, is an extremely poor conductor of heat; experiments show that the loss from scale 1/16 to ⅛ in. thick is from 10 to 12 per cent., scale ¼ inch thick often causing a loss as high as 30 per cent. The boiler acts as a catch basin for impurities in the feed water; a 500 h.p. boiler containing about 40,000 lbs. of water, when operating at 150 per cent. of rating, uses about 26,000 lbs. of water per hour.

Assuming that the feed water contains 17 grains of impurities per gallon; with the boiler operating at 150 per cent. of rating every 10 hours, there are introduced into the boiler 26,000 x 17 or 442,000 grains of impurities. The 4,000 gallons on starting with 17 grains per gallon of impurities would then contain 110 + 17 or 127 grains per gallon, of which 52 are encrusting solids.

Little wonder then that boilers scale up, unless care is taken in keeping the feed water comparatively free of impurities.

Causes Trouble in Steam

No boiler makes dry steam, always carrying some moisture over to the steam lines or the superheaters. If the steam carried only 1 per cent. of moisture, about 26 gallons of water per hour would be carried out of the boiler and with it approximately 63 grains per gallon, or in ten hours about 3 lbs. of encrusting solids would be deposited in the superheater or carried into the steam lines.

These scale-forming substances are extremely hard on turbine blades.

The soluble potassium and sodium salts react with any organic substances of vegetable or animal origin, forming compounds not unlike soap, which cause resistance to the liberation of steam evidenced by the formation of bubbles that agitate the surface, and in extreme cases violent upheaval of the water in the whole boiler.

The mild surface agitation is called "priming," the more violent is known as "foaming."

Corrosion by Acids

Corrosion is the most dangerous of all ills resulting from impurities in the feed water, especially when deposits of scale hide the extent of the action of the acids causing it. Feed water may contain no free acid, but the breaking down of unstable compounds of iron, calcium, or magnesia, may form acids within the boiler.

The use of stokers and large water tube boilers, operated at high ratings, has compelled power plants to purify the boiler feed water, if they wish to maintain high efficiencies or prevent excessive cleaning and repair bills.

The Ideal Feed Water

A good water for boiler feed purposes would include:

Complete removal to zero of oil, grease, iron, free carbonic acid, and carbonates as well as all suspended matter.

Complete removal of substances causing permanent hardness.

Complete removal of substances causing temporary hardness to such a point that the residual calcium and magnesia are below their solubilities in water at 212 deg. F.

Complete conversion into harmless substances of all acids or acid-producing substances such as certain compounds of iron, alumina, manganese and magnesia.

A reduction of slightly soluble silica and other compounds.

The concentration of soluble compounds and the precipitates in suspension in the boiler can be kept within the limits for good steaming by blowing down and changing the water at proper intervals; there is then no danger of priming or foaming.

Saves Money

At the present time it is not enough to define a boiler feed water as free of acids, without visible suspended matter or with incrusting solids not over three grains per gallon. Water softening apparatus with continuous flow can give only an average reduction in encrusting solids; there is left a high percentage of suspended solids and soluble substances, tending to produce priming and foaming unless the boiler is blown down and water changed at frequent intervals.

That standardized softened water for boiler feed will save money is shown by the two following cases:

In an industrial plant with 4,000 boiler H. P. using 100 per cent. make-up, where formerly a compound was introduced in a water containing about 12 grains of scaling solids per gallon, the following are the savings for the first year of operation:

Heater and Boiler Cleanings ..	$1,650.00
Tube Renewals and Repairs ..	6,000.00
Fuel	3,215.00
Total	$10,865.00

Total steam production increased 13 per cent.

Cost of steam production reduced 25 per cent.

Another case shows not only a saving in the boiler room but also in the turbine. This 6,000 boiler H. P. station uses about 20 per cent. make up containing 16 grains of scaling solids per gallon. After changing to a standard feed water from a softening machine, which gave an unknown variation in the amount of scale-forming solids left in the water, the following savings were made during one year of operation:

Boiler Cleanings	$ 950.00
Tube Renewals	1,050.00
Elimination of turbine blading lowered water rate with dry steam	8,800.00
Fuel saving from increased efficiency in boilers	3,000.00
	$13,800.00

Draft Usually An Expensive Thing To Produce

Proper Design of Stacks and Passages Essential for Maximum Economy and High Ratings; Excessive Draft Almost as Bad as Insufficient Draft in Reducing Efficiency

DRAFT, to many engineers, is something to be forgotten except when an unusually bad shipment of coal makes it impossible to keep up steam, or when it is desired to carry an extra overload for a short time.

Few plants are designed with any reserve capacity in draft and when the passages become filled up in time with soot, the condition becomes worse. The cost of providing sufficient capacity is negligible compared to the cost of a reserve boiler. The engineer who is in charge of an installation with good draft must exercise his best judgment in the use of the damper or he may turn a blessing into a curse by pulling large amounts of excess air through the fire, resulting in low CO_2.

Draft can be defined, precisely speaking, as the flow of air through the boilers and flues; but as it is usually out of the question to measure this directly, it is inferred from pressure measurements at various points.

Most modern plants have well proportioned and arranged stacks and flues, but many older plants were not so carefully planned. Where changes and additions have been made, plenty of chance for trouble exists.

It will therefore pay an engineer on taking over a new job, to make a survey of the draft pressures from chimney to ashpit, taking pressures in each individual boiler until he is satisfied that the readings obtained are really representative of average conditions. If a number of inclined tube draft gauges are available, they are very convenient for this work.

To Take Readings

Reliable results can, however, be obtained with a single U-tube gauge filled with water, as readings can be estimated to within .02 in. of water. It is best to drill holes in the flues at the proper points. Through them a short piece of 1/8 in. pipe, connected to the gauge by rubber tubing, can be entered so as to extend about six inches to a foot inside the flue.

Boiler drafts can be measured through cracks or openings in fire doors, soot-blowing doors, etc. To obtain the best results, the pipe used should be cut off square at the end and held at right angles to the direction of flow. Where possible, openings for taking drafts should not be located at a bend in the flue as the eddies are almost sure to give inaccurate results.

After the readings have been obtained and the averages tabulated for different conditions, it can easily be seen from the drop in draft pressure where the greatest resistances are. That part of the gas passage should be specially examined to locate the trouble.

To Figure Draft

Very complete tables and curves, from which the available chimney draft and probable friction loss may be figured for any set of conditions, are given in the handbooks issued by the larger boiler manufacturers. However, these are usually predicated on more accurate knowledge of quantities, etc., than is generally available.

There is a prevalent idea that the purchase of advertising space carries with it an unwritten right to notice in the editorial pages. This may have been so in the bad old days but it certainly is not so to-day. Reputable publishers are proof against blandishments of this kind, for very little thought will make it evident that such a policy would be an extremely destructive one for an advertiser to follow. Were this plan put into effect newspapers would be filled with matter selected not for its news interest but for its revenue-earning capacity. Lack of interest means loss of circulation, and as after all, the advertiser is primarily concerned with circulation, particularly circulation of the right kind, it is evident that by retaining the interest of the best type of reader the editor indirectly best serves the advertiser.

An approximate rule, therefore, of ½-in. of water available draft at the base of the stack for each 100 ft. of chimney height, and a friction loss of 0.10 in. of water for each bend in the gas stream, neglecting friction in the straight runs of the flue, will be a good working guide for the average plant where there are no excessively long runs.

The friction loss in the boilers themselves varies widely with the type and size of the boiler and the baffling, but if more than .15 to .20 in. of water resistance is found between the firebox and damper for two or three pass boilers up to 500 h.p., operating at rating, there is probably an excessive accumulation of soot in the tubes or dust chambers. For other rates of driving, this draft loss will be in proportion to the square of the capacity developed.

That is, at 150 per cent. the resistance would be 2¼ times the above, or .34-in. to .45-in. of water; at 200 per cent., 4 times, or .60 to .80-in. of water.

True Friction Loss

The measurement of the true friction loss in draft through a boiler is complicated by the hot gases inside the setting. Just as in a chimney, due to their lesser density, these give a difference of pressure as compared with the outside air when they are measured at different loads. Where the friction loss is small and the difference in level considerable, as in a vertical fire-tube boiler at low ratings, there may be an apparent paradox in that higher draft may be found in the fire-box than in the smoke connection.

This is noticeable in burning high-sulphur oil in boilers without ash-pit door air regulation. When the flue damper is closed enough to bring the air supply down to a reasonable amount, there is a positive pressure in the smokebox, and the sulphur dioxide almost drives the working force out of the boiler room.

In general, however, the worst draft troubles will be found in the flues.

A convenient rule for proportioning gas passage areas for boilers which are not to be forced over 200 per cent. of rating is: damper area 1/6 grate area, flue area 1/7 grate area, and the stack area 1/8 grate area.

Typical Example

In one plant which had a self-supporting steel stack, 7 ft. 6 in. in diameter, 200 feet high, with a steel flue entering on one side by an opening 5 ft. wide and 7 ft. 9 in. high, served two boilers of 375 h.p., two of 240 h.p., and two of 330 h.p. each. Boiler brickwork and flue joints were in good condition, the flues were clean, yet not over 125% of rating could be carried. The grate area of all boilers was 378 sq. ft., flue area 62.2 or 1:6. 24, opening into stack, 36.7 sq. ft., or 1:10.30, and stack, 44.2 sq. ft., or 1:1.855.

It is seen that the trouble lay with the opening in the stack. After this was enlarged to 5 ft. by 9 ft. 10 in., giving an area of 49.1 sq. ft. and a ratio of 1:7.68, it was found to develop 160 per cent. of rating where 125 per cent. had been the maximum before.

No matter what the rating of the boilers a certain intensity of draft is required to operate at a given rating; a corresponding height of stack being required to furnish this.

In a street railway power house, when stokers were installed, the stacks were found to be too short to give an appreciable increase in rating. After the stacks were heightened, a much greater capacity was secured from the same boilers.

Vacuum Necessary

It is essential to keep a vacuum of at least .10 in. in the firebox at all times if the firebrick is to be protected, savings in repairs from 50 to 75 per cent. may result, comparing with a steadily maintained positive pressure of .02 to .03 in.

With a slight vacuum there is always a small infiltration of air through the pores and crevices of the brickwork, tending to cool it and preventing rapid burning of the wall; on the other hand, if pressure is in the furnace, the flow is outwards, tending to keep the brickwork excessively hot.

This is one of the difficulties of the very high furnaces found on certain types of boilers, since, owing to the high temperature of the furnace gases, the chimney effect of the setting is nearly .01-in. of water per foot of height. Consequently if there is a vacuum in the furnace at the grate level of .10-in. of water, this has all disappeared at a height of 10 ft. above the grates. Above that there is a positive pressure which is very hard on arches unless ample precautions are taken for proper cooling.

Different Air Supply

Another tendency where draft is limited is to run with a somewhat deficient air supply and this causes furnace temperatures at comparatively low ratings which would not be reached with ample draft and air supply at much higher ratings. There is consequently much greater clinkering of the coal ash and burning of it into the walls.

In considering the disadvantages of insufficient draft, no one should think that there cannot be too much. Excessive draft is almost as bad in its effect on economy. This is chiefly due to the very large quantities of air drawn in through every crevice and opening around fire, tube, and cleaning doors.

This takes up heat to raise it at least to steam temperature and passes off to temper the surrounding climate. Besides the larger volume of gases passing through the boiler reduces the heat absorbed from those which came from the fuel bed. This also decreases the boiler efficiency.

Steam is Wasted

When this condition is due to unregulated chimney draft, it is bad enough. In a great many plants with induced draft fans, however, steam is being wasted to create this excessive draft.

One power plant which had both a 175 ft. brick stack and also an induced draft fan, installed on account of a very long, double economizer, reduced coal consumption per kilowatt hour 10 per cent. by enforcing a regulation that the fan was not to be run except when the load rose above a figure determined by careful tests.

Sometimes it is possible to turn such excess of draft to good account by rebaffling the boilers to increase the gas velocity and thereby the absorption of the heat. Induced draft fans should always have variable speed control, whether steam or electric driven.

Modern tendencies toward large units, high capacities with correspondingly high pressure drops through the boiler settings, and, often, economizers in addition, undoubtedly call for induced draft fans. It must be remembered, however, that such apparatus calls for a much higher degree of intelligence for economical and safe operation and that the field of such designs is a public service station load with comparatively short high peaks which must be carried without a prohibitive expense for boilers and buildings to house them, usually in an expensive location.

Factory Load Varies

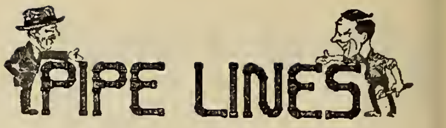
Conditions for the average uniform factory load, particularly if it is a 24-hour day plant, are quite different. In the latter case the investment charge becomes a smaller proportionate item compared with the fuel bill, and the plant should be designed with a view to operation at its point of maximum efficiency both in heat absorption and repairs.

For such service the choice and arrangement of the equipment must be determined by the fuel supply offering the most heat units for a dollar, the power required, and the size and shape of the space available. Where these are rather limited, a satisfactory solution will often be a return to the old arrangement of individual stacks for each boiler, or at least each battery, supported on the boiler framework and cross braced between themselves. This has the further advantage of extreme flexibility in case changes in capacity are required, since the individual stacks can be heightened or new batteries added without crowding the capacity of one old stack or the flues.

In general it must be borne in mind that draft is an expensive thing to produce, whether by steam power direct on a fan, or by a chimney which any thermodynamics book will prove is a very inefficient heat engine. It should be used as economically as possible by making the flue passages short, straight and of nearly uniform area, possibly contracting slightly in proportion to the cooling of the gas to keep the velocity constant.

The nearer we approach these conditions, the higher capacity can be obtained from our present equipment, or if we are arranging a new installation, the less it will cost to provide for proper draft facilities.

A small piston rod can be removed from the crosshead without scoring with a Stillson wrench by using two hardwood blocks hollowed out to fit the rod and bolted to it by means of four ½ in. bolts. A piece of sandpaper should be placed between the rod and the blocks which, when clamped to the rod, have a space between them. The blocks afford a place to put a wrench and turn the rod out of the crosshead.



PIPE LINES

UNCOVERED IN ANY OLD SPOT

In packing a flange or cylinder with a rubber gasket, all oil and grease should be wiped from the surface of the metal.

* * *

There's a fireman in Guelph who wears his girl's picture in his watch case because he thinks he will learn to love her in time.

* * *

The length of a connecting rod depends much upon the design and duty of the engine. For large stationary engines the length of the rod is 2½ to three times the stroke of the piston, if space permits; on smaller engines the ratio is sometimes reduced.

* * *

If a bathing beauty were looking for a date would the water-meter?

* * *

The cut-off valve on the low pressure cylinder is used for adjusting and equalizing the work performed by the steam in the high and low pressure cylinders.

* * *

"Income tax," grumbled the carpet, as the engineer got busy with his hammer.

* * *

An ordinary cross-compound engine can be started without prying on the flywheel by admitting steam to the low pressure piston by means of the bypass valve on the receiver, in case the high pressure crank is on the center.

* * *

F stands for furnace and fireman, too; when both tend to business the coal man looks blue.

* * *

The dashpot of a Corliss engine should have a plentiful supply of machine oil or oil of a heavy grade or glycerine. The temperature of the engine room will determine to some extent the heaviness of the oil.

* * *

When your boiler efficiency refuses to "fish" examine the heating surfaces.

* * *

Frequently the sight-feed glass of a lubricator fills with oil. If the oil is removed from the body of the cup and it is filled with water and started up in the usual way, the water will float the oil out of the glass without further trouble.

* * *

Within a bar magnet the flux runs from the south to the north pole, and without the magnet from north to south.

Steam Turbines Cut Cost of Auxiliary Drive

When Low Initial Cost, Reliability and Limited Space Are the Deciding Factors, This Type of Drive Becomes a Real Power Plant Economy

DURING the last few years the use of the steam turbine for driving the auxiliaries in a power plant has kept pace with the progress made by its larger brother, the main turbine, more especially in its application in the boiler room proper.

Speaking first of fans for induced draft, it is, of course, necessary either to drive them electrically or by steam.

In the past, the steam engine, with its low speed, has been used to drive fans of very large diameter. But that type of drive is gradually giving way to the small, high speed turbine driving the fan of small diameter.

The results of this, as far as volume of air is concerned, and economies, are usually good. The advantage of the small set, however, is found in the limited space required for it, both in floor area and head room, the comparatively few working parts, the low first cost and upkeep.

There are mighty few parts to get out of order in a turbo-fan where there is only one rotor in the turbine and one rotor in the fan. These are usually connected through a flexible coupling unless some special requirement calls for a reduction gear between them. Such cases are comparatively rare.

Two Points to Pack

With only one rotating element, it might be said, there are only two points to pack against leakage. The turbine is packed against steam leakage with carbon non-leaking ring packing, which will last a long time. The fan needs no packing; hence the plant has a unit which merely requires unskilled labor when it comes to turning the throttle valve of the turbine on or off.

In the boiler feed pump, however, there is more to be said. The old style reciprocating pump, of course, is large. The matter of packing it is more or less troublesome, as the plunger action is reciprocating and therefore a wearing one upon the packing, as against the turning motion of the centrifugal pump shaft with its tendency to "wear in" the packing so that it will hold tight.

Another fact—centrifugal pumps have no valves, whereas, reciprocating pumps have them on the suction and discharge.

Simple Control Equipment

A turbine pump can be allowed to operate until boiler pressure is reached and the pump is working against what is called "shut off pressure." This is usually about 1.2 times the operating head. The pump is developing no water but is really balancing a column of water against the boiler pressure. The only effect is that the impeller of the pump churns the water but uses very little power in doing so.

This type of pump, of course, requires little head room. The turning action of the pump impeller shaft is such that it wears the packing in and really makes it tighter than when it is first placed in position.

Speaking generally of steam driven auxiliaries in the boiler room, as against any other type such as electrically driven, it has been found advisable by some engineers, to install not only electrically but steam driven auxiliaries. In other words, it is good practice to install a "break-down" unit in a power plant of any size.

Every engineer knows that an overcoat does two things. It keeps the heat in and the cold out. But engineers forget once in a while that steam piping needs an overcoat just as much as they need one. And for the same reason. An overcoat on piping keeps the heat in and the cold out. The name of this overcoat is "insulation." Pipes that are uncovered waste much heat, which means that they waste much coal. To do without an overcoat, cut to fit your piping, is to waste about one fifth of your fuel. And at present day prices you can't afford that, can you?

Auxiliaries Must Not Fail

It is often the case that the electric power will fail, for some reason or other, or be turned off, and when that is true, then the auxiliaries, such as the boiler feed pumps, which are vitally necessary to operation, must cease, and the boilers must be shut down.

On the other hand, with steam driven auxiliaries, the electricity may fail in the main generating-unit, but the auxiliaries go on just the same as ever and the boilers are kept operating at normal, ready to take the load just as soon as repairs have been made to the generator.

Practically all boiler auxiliary drives operate non-condensing against a back pressure. In other words, the steam is required for feed water purposes. Such being the case, economy in the turbine is not paramount but consideration is given to the construction of the turbine, its ability to operate under severe conditions in, usually, very dirty "un-get-at-able" locations. They must be designed for continuous operation with practically no attention.

Maintains Heat Balance

In some plants where it is required, the question of heat balance enters and in such cases both electrical and steam auxiliary units are operated. Often a motor and turbine will be connected to one centrifugal pump, the turbine at one end, the motor at the other. The turbine is on the thermostatic control.

When the temperature of the feed water drops, the turbine operates, the exhaust from which goes to the heater and raises the feed water temperature to the desired point. It then shuts down.

At this point the motor begins operating, and drives the pump. Hence no heat is lost—all exhaust steam is consumed either in the steam auxiliary or the main generating unit. This, however, is not a matter of first consideration if there is use for exhaust steam from the turbine auxiliaries. If such is the case, then it behooves the engineer for one of several reasons, as above given, to be somewhat sure that his auxiliaries will operate for all conditions, that his boilers will always be regularly fed and that his induced fans will rotate just as long as is necessary.

Bleeder Type Useful

It is only within the last year or so that the "bleeder" or extraction turbine has been commercially possible for use in sizes small enough to be used for auxiliary drive purposes. This type of turbine furnishes the ideal method of heat balance in the boiler room and replaces the combination motor-turbine drive of the pump or fan.

In practice, the "bleeder" turbine is direct connected or geared, as necessity dictates, to the centrifugal boiler feed pump or fan. Steam at boiler pressure expands through the velocity wheel stages of the "bleeder" as the case may be, to the desired back pressure. An automatic diaphragm "bleeder" valve operated from the "bleeder" pressure system regulates the volume of back pressure steam which is "bled" to the feed water heater. The governor valve regulates the high pressure steam flow to the turbine.

Steam which is not needed in the back pressure system expands through the remaining pressure stages of the turbine to the condenser vacuum, thereby furnishing additional power with which to drive the pump or fan. This automatically decreases the amount of boiler pressure steam used in the auxiliary.

Slavery Man's Original Conception of Power

By **PAUL T. BRADY***

Take Power Away From Us—Leave Us With Nothing But Our Bare Hands, and We Could Do Little More Than Keep Ourselves Alive

WHO was the founder of civilization?

This may appear to be one of those idle questions which anyone can ask and no one can answer; but I have an answer to it, and I am sure you will all agree that I am right. The founder of civilization was that prehistoric leader who first said in effect, "Boys, I have an idea. After we have beaten up that outfit across the river, we won't eat the prisoners this time—we'll make them work for us."

Here was the original conception of power—the means for doing work. Though the inventor did not know it, he had hit upon the one thing that enables men to rise above savagery. Take power away from us—leave us with nothing but our bare hands—and we can do little more than keep ourselves alive. Give us power, and there is no apparent limit to our achievements.

First Labor of Slaves

The earliest form of power was the labor of slaves. This was, of course, deplorable; it was highly inefficient; and it possessed the great drawback that the engineers were liable at any time and without notice to become the machinery. Nevertheless, had not men been enslaved, Thebes, Babylon, Athens, and Rome would never have existed, and we would still be living in camps and caves.

The use of draught animals was a great advance over slavery, and gave us the Europe of Shakespeare, Montaigne, and Goethe. Then came Watt with his steam engine, and Fourneyron with his hydraulic turbine, and Edison with his central electric power station; and with each improvement in the methods of generating and distributing power, society made immense strides forward. Today we are living in the age of the long-distance transmission of alternating-current electricity, the age of modern miracles.

But were the great inventor alive today, he would be the first to warn us that we must not stop here. He was always a generation ahead of his time, and it would be clear to his far-sighted vision that the work he did forty years ago has reached fruition and that we must now plan anew for the benefit of our children's children.

Fortunately, we know what the next step should be, and we are fully equipped to take it. We must now give everyone in Canada and the United States an abundant supply of electricity; and we must do this by putting our water power to work and, pouring all of this energy into a single great international network, distribute it to practically every inhabited portion of the continent.

It may be safely said that readers of Power House direct all progress in power plant operation in Canada, for few men in the field fail to realize that the broad, constructive policy of that newspaper is of inestimable value to the engineer wherever he may be. The best efforts of Power House are in its editorial pages and not in its advertising solicitations—which probably accounts for the position of leadership it steadily maintains.

This plan, which is known as the "super-power" plan, represents the consensus of the opinion of all competent engineers who have studied the subject; and though gigantic as the task may be, we can rest assured that it will eventually be carried out.

But as man cannot live by bread alone, neither can a power system live on water alone. With few exceptions all rivers vary greatly in their seasonal flow. The upper waters of the Hudson, for example, are able to generate 500,000 horse power at high water, but in dry seasons, the flow is greatly diminished. Similar conditions obtain with the Chippawa and all the others. It is recognized, therefore, that the most economical and reliable method of generating power is by means of a system using both water power and steam power. When water is abundant, the water-power plants carry the main load of the system, and only enough steam power is used to take care of demands in excess of the capacity of the water-power plants.

In this way, the consumption of fuel is reduced to a minimum. But in dry seasons, operation is reversed. The steam plants now supply the main load, while the water-power plants are shut down for the greater part of each 24 hours so that they can accumulate enough water in their storage reservoirs to take care of peak and emergency demands. In this way a continuous supply of power to meet all requirements, is provided.

To Supplement Water

Hence, to take the next step in social progress, not only must we utilize our water-power resources to the fullest extent, but we must also use huge steam plants which will supplement the water powers. The ideal location for these steam plants is beside the rivers, where fuel can be delivered to the boilers with a minimum of transportation and where ample supplies of condensing water can be obtained. But there is a tendency on the part of certain power engineers connected with plants thus favorably located to take a short-sighted view of the power situation.

"Why should our plants co-operate with water-power plants?" they ask. "We can gain nothing by becoming part of a larger system, and are therefore not interested in the project."

These people forget that outside the narrow limits of their own systems there are millions of people who are either paying high prices for electricity or are unable to get it at any price.

They forget that their properties form an essential element in any plan to supply the country as a whole with power at the lowest possible cost. They forget that, if their plants become a part of such a system, they will have the widest possible market for their excess power and their surplus coal. They forget that after all their systems are not absolutely self-sufficient, and that, unless connected with other sources of power, they may fail to give service in event of serious accidents. And finally, they forget that it is precisely this attitude of self interest that forms one of the strongest arguments for the governmental ownership of the unified power system.

They must see the larger picture. Up north in Canada, there are 18 millions of horsepower of the finest water power in the world; down here in Pennsylvania, West Virginia, and Ohio there are billions of tons of coal. Employed separately, each will indeed benefit many people; but used together to the best advantage, they will bring ever increasing prosperity to all of the people in Northeastern North America— in other words, they will usher in the next age in the history of civilization.

Production and Possibilities of Lignite Char

By O. P. HOOD, A.S.M.E.*

Lacking Abundance of the Best, Manufacturers Are Impatient With the Limitations of Lower Grade Fuels Forcing Canadian Output to Compete With Anthracite

THE greatest difficulty with lignite is the fact that in nearly every district where it should be the natural fuel it is put in competition with high-grade fuel. We are all spoiled by having been blessed with an abundance of the best, so that we are impatient with the limitations of lower-grade fuels.

If we had been obliged to go down 2000 ft. or more and win good coal from thin seams in scattered districts as they do in Europe, we would have long ago worked out a successful technique for utilizing our lignites.

Canadian and North Dakota lignite must compete with anthracite and with Pittsburgh and Illinois bituminous coal; Texas lignite must compete with gas, oil, and Oklahoma bituminous coal. It is evident, however, that there must be a price at which the lower-grade fuel will begin to be attractive.

In round numbers the ratio is somewhere in the neighborhood of half the price of good coal. With the rising price of bituminous coal we are fast approaching the time when this ratio will be common.

The handicaps of lignite are well known, but not always properly valued. The heating values of high-moisture fuels are somewhat misleading. The heat carried by the moisture is recovered and measured in the calorimeter, but is not fully utilized in a boiler furnace. The B. t. u. ratios, therefore, do not give the relative possible steaming values of the fuels if comparison is made between a high-moisture lignite and a low-moisture bituminous coal. Although the ash percentage may be low, there is usually a larger total amount of ash to handle in a plant using lignite.

The fusing temperature of the ash is usually low, making high rates of combustion difficult and requiring larger grate areas and furnace volumes than with higher-grade coal. Notwithstanding these handicaps, with present technique, raw lignite can be used in large operations, and good efficiencies and reasonable capacities can be obtained. The problem is largely an economic one. When raw lignite is cheap enough in comparison with better coals it will be used in large steam-raising operations.

Search Must Continue

The search for a means to improve the fuel, however, must continue. A fuel classed as lignite in Northern Bohemia, and weathering much as does our lignite, is as carefully prepared for market as is our anthracite. Seven prepared sizes are offered to the market. Raw lignite can probably be somewhat improved for steam raising by sizing the product more closely than is common practice. It is probable, however, that an improved lignite product must first cater to a special trade that will pay a special price.

This is illustrated by the vision that has been so frequently held of improving the lignite by some process involving briquetting.

Unlike the German "Braunkohle," lignites do not make a stable and satisfactory briquet simply by drying the lignite and briquetting by heat and pressure. They lack sufficient inherent binder to consolidate and waterproof the mass. The necessary added binder increases the cost and hardly improves the quality. A quite satisfactory fuel can, however, be made by briquetting lignite char, and it is probable that some day such a fuel will be in common use.

Lignite char is lignite which has been dried and distilled in an oven especially designed for the purpose. About two and one-half tons of raw lignite reduce to one ton of char, the heating value of which is about 12,000 B. t. u. per lb. While raw lignite can be used satisfactorily in large steam-raising operations the author believes that the search for a means to improve the fuel must continue. Lignites do not briquet well without the addition of a binder, and the Bureau of Mines has therefore been led to investigate the possibilities of an inexpensive carbonizing process and the use of the resulting lignite char direct without briquetting. This process is briefly described in this article.

May Cut Costs

There have been hopes that through the recovery of by-products sufficient credits might be obtained to materially lessen the cost of briquets. Profit can be shown on paper, but such a process is essentially a large-scale operation requiring a large investment and very substantial financial backing by those familiar with technical enterprise. It is difficult, therefore, to start such an industry, for there is no opportunity to begin small and grow up, returning profits into an improved plant. Capital familiar with technical enterprise finds less hazardous ventures, and capital unfamiliar with such enterprise is apt to be misled and lost.

With these facts in mind, the Bureau of Mines is investigating the possibilities of a somewhat different program which has for its main features an inexpensive carbonizing device and the use of the lignite char direct, without briquetting. If a market for the char can be developed, and the small mine can produce char, there would be provided means for a natural evolution of an industry that in time might realize the larger vision of briquetting and recovery of by-products.

To Describe Char

Lignite char can best be described in a few words as a fuel rather than in analysis with anthracite coal, but softer, with a little more volatile matter, and thus kindling easier. In size it grades from pea coal to smaller sizes, and is a stable product. Whether a market can be developed for such a fuel at prices around five dollars a ton at the mine, remains to be shown, but it is at least encouraging to know that Germany used last year 400,000 tons of similar material for domestic heating and cooking.

This fuel burns well with natural draft where a thin fuel bed, about 1½ in. in thickness can be maintained. Base burners, cook stoves, and other heaters can be adapted to use the fuel satisfactorily. The Germans have developed a special stove, burning the fuel on a bed of ash in an enclosed drawer. There is no loss of fuel in the ash and lignite char used in such a stove heats an oven sufficiently for baking operations and will boil water. It makes a very clean fire, is smokeless, and the chair is clean to handle. It is, however, slow in getting under way as compared to a gas range.

Devise Simple Oven

To produce the char a very simple oven has been devised that greatly reduces the investment from that needed for ovens heretofore proposed. If lignite be passed through a combustion zone, moisture is first driven off; then combustible gases are distilled, and finally the solid carbon is burned. There is considerable shrinkage in volume and a complete absence of caking quality. These steps are fairly distinct, one from the other, so that the flow of lignite through the combustion zone may be so regulated that but little of the fixed carbon is burned.

*Presented at the Spring Meeting in Montreal, May 28 to 31, 1923, of the American Society of Mechanical Engineers.

C. A. S. E. Notes

At the last regular meeting of the C. A. S. E. No. 9, on Friday evening, May 25th, a lecture on steam turbines was scheduled, but owing to the lengthy discussion of different resolutions, the lecture was postponed until the next meeting. Bro. Nelson Levan, formerly assistant engineer at the Waterloo Water Works, is now assistant to Bro. Walker, of the Kitchener Water Works. W. Hirst is assistant to Bro. Beam, taking Bro. Levan's place at the Waterloo Water Works.

C. OTT, Rec. Sec.
Kitchener, Ont.

Book Reviews

Mechanical testing.—Testing of Prime Movers, Machines, Structures and Engineering Apparatus. By R. G. Batson and J. H. Hyde (both of the National Physical Laboratory, Teddington, England). Published by E. P. Dutton & Co., cloth, 5½ x 8½ in.; 446 pages; 313 illustrations. $10.

This volume covers its field in a thorough manner. Considerably more than half of it is of direct interest to engineers concerned with the testing of power equipment. The discussion of dynamometers, which occupies 127 pages and is accompanied by nearly a hundred illustrations, is particularly comprehensive. Absorption, transmission and traction dynamometers are treated separately and in detail.

Steam Turbine Principles and Practice. By Terrell Croft. Published by McGraw-Hill Co. Cloth, 5½ x 8½ in.; 347 pages. $3.

This book was written for those who operate steam turbines or manage properties containing such machinery. The subject matter has been designed to supply the man who operates with the necessary facts to do so economically, and those who purchase steam turbines, with the information that would lead to making a wise choice. The fundamental principles are described and connections to some of the basic formulas illustrated.

The advantage of running an engine over is that the pressure of the crosshead is always downward upon the guide. If the engine is run under, the thrust of the crosshead would be upon the top guide on both the outward and inward strokes, and unless the crosshead is properly adjusted, it will lift when subjected to thrust and fall by its own weight on the centre, making the engine pound.

The thinner the packing between a cylinder head and the cylinder, the better. Thick packing is more likely to blow out, and the additional thickness unnecessarily increases the clearance in the cylinder.

Operating at a 3,200 Lb. Pressure

New Method Now Being Tried in England to Increase Power Plant Efficiency

A METHOD, looked upon as promising by engineers who desire to increase the thermal efficiency of steam-power plants, is to raise the pressure and temperature of the steam and so design the prime movers as to utilize efficiently the increased energy drop thus made available.

Experimental plants have been satisfactorily operated with steam pressures ranging up to 1,500 lb. per sq. in. and the chief difficulty found at such pressures has been in the generation of the steam rather than in its use in the turbines.

Extraordinary precautions must be taken in design to guard against priming, or the passing over of water in gulps, on account of the violent boiling of water at this pressure and it has been principally due to the seriousness of this factor that pressures above 800 lb. per sq. in. have been attempted in only a very few cases. The likelihood of priming increases as the pressure is raised so long as steam is generated by methods that require the addition of latent heat with the consequent boiling.

One hundred years ago James Watt assailed Richard Trevithick as a "murderer" for proposing to operate boilers at the "dangerous" pressure of 60 pounds. To-day, there is nearing completion at Rugby, England, a plant designed to operate at a minimum pressure of 3,200 lb. Perhaps the most interesting feature of this plant from the Canadian engineer's point of view will be the generation of steam without boiling, by operating the steam generator in what may be termed the "super-pressure" region; that is, the region above the "critical point."

Favors Big Jump

The tremendous advance, however, made recently in the production of high-tensile steel and steel alloys has induced an English designer, the Benson Engineering Company, Ltd., of London, to introduce a super-pressure plant using steam at a pressure of 3,200 lb. per sq. in. and a temperature of 706 deg. F. The tremendous jump to 3,200 lb. being due to the fact that at any pressure below this, latent heat must necessarily be added, with the consequent troubles from boiling and priming.

This experimental test plant, soon to be erected in the works of the English Electric Company, at Rugby, England, is equivalent to a 1,000-k.w. commercial plant. Steam will be generated at a pressure above 3,200 lb. per sq. in., then throttled to 1,500 lb. and, after being superheated to 788 deg. F., will be passed through a high-pressure turbine exhausting at 200 lb. per sq. in.

To Reheat Exhaust

The exhaust of the high-pressure turbine is to be reheated to 662 deg. F. and then expanded in a standard normal-pressure turbine to 29-in. vacuum. The builders of the plant predict not only that it will consume about 28 per cent. less fuel than a high-grade plant of the same capacity operating at 250-lb. pressure, but that it will be cheaper to build and maintain.

As a matter of fact the actual test generator, complete with feed pump and fan, has cost less than a normal water-tube boiler of the same kilowatt capacity even though every part has been special.

The plant exemplifies one of many possible arrangements using steam generated at the critical point. The fundamental ideas involved in this method of steam production are covered by patents granted to Mr. Benson.

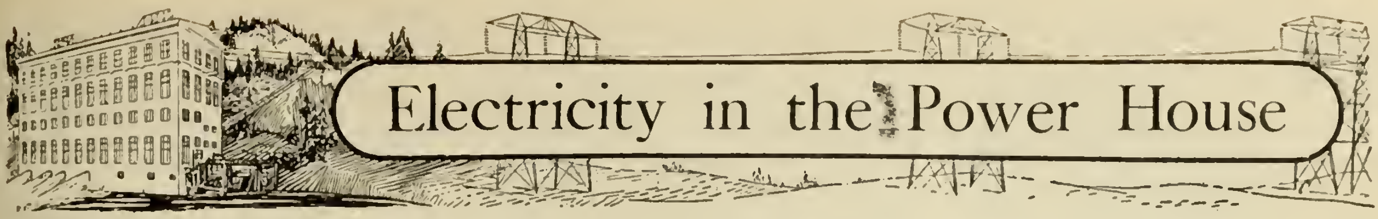
Owing to novel features in the high-pressure turbine, details of the design are not available for publication, but it may be said that the experimental turbine will have only one impulse wheel of a very small diameter, which will rotate at from 20,000 to 25,000 r.p.m.

Expansion will take place in the nozzle of this high-pressure turbine from 1,500 lb. and 788 deg. F. down to 200 lb., corresponding to an adiabatic heat drop of 196 B.t.u. The high-pressure turbine will eventually be gear-connected to a standard low-pressure turbine which will run at 6,000 r. p. m.

On account of the very high pressures and temperatures carried, special provision had to be made for the shaft and valve-spindle packings and attention has been given in the design to the restriction of windage and friction.

When the length of a connecting rod is reduced by constant keying-up, it results in the piston travelling much nearer to the front of the cylinder head. To prevent this shims are used back of the brass, next to the crankpin and the wristpin centre is lengthened by keying-up, and the shims should be placed between the brass farthest from the rod; that is, between the brass and strap.

An automatic cut-off engine regulates its speed by cutting off the steam supply according to the load, thus using a greater degree of expansion than when, as in the throttling engine, the cut-off is late enough to carry the maximum load. The slide-valve throttling engine regulates its speed by throttling the steam between the boiler and the cylinder.



Electricity in the Power House

CARE OF TRANSFORMERS

THE increasing utilization of electrical energy, cheaply generated in either large efficiently operated steam plants or hydro-electric stations, renders it now almost always necessary for large consumers to obtain their current at high voltage and transform it down to a suitable one for general works transmission.

In itself, the modern transformer, having no moving parts is a comparatively simple piece of apparatus, at the same time care is called for in its installation and maintenance.

As a rule the makers despatch transformers, when of moderate size, as complete units, and presuming these are oil cooled, as is now generally the case, they may be sent in their tanks with sufficient oil to cover the coils or without oil, the latter being sent separately.

In order to prevent movement during transit, however, wood packing frames are inserted between the transformer core structure and the tank in order to prevent movement of the transformer itself during transit. It is the business of the makers to see that these packings are quite free from shavings or sawdust which might find its way between the windings.

Bolted In Position

Finally the tank cover is bolted into position. Whether the whole comes in a crate is a matter for the makers to decide, but exposed terminals outside the tank are protected by a wooden cover.

It is important that this be done in a dry situation, because damp or moisture in a transformer is a very troublesome matter. The whole affair should be lifted from its tank and the windings, terminal leads and insulators carefully examined for any signs of abrasion, breakage and the presence of moisture.

If the tank arrives without oil it should be thoroughly cleaned out. All nuts should be gone over, tightened and locked. Where the transformer is fitted with adjusting tappings care must be taken to ascertain that the various connections are made in accordance with the diagram of connections. After a complete examination the transformer may be replaced in its tank and if necessary dried out.

All transformers, wound for high tension pressures of 6000 volts and over, should be dried out immediately prior to their being placed in commission, and the oil should be dried out also.

For lower voltages if despatched out of oil it is well to dry out if delayed in transit.

The drying out of a transformer is a job that requires care. Both the oil and insulating materials are liable to absorb moisture, which it cannot be too strongly impressed is detrimental.

There are two general methods of performing this important operation, that is:—

(a) By Oil Immersed Resistance Heating.

(b) By Short Circuit.

Method (a) consists of drying out the transformer and oil simultaneously in the transformer tank by means of specially constructed resistance units which are lowered between the windings and tank to the bottom of the latter. It is first necessary to clean down and make sure there are no foreign bodies in the tanks; the transformer is placed therein and oil poured in to the working level, or in the case of tubular tanks just below the top of the cooling tubes.

Do not grumble too much! If you do, your employer will think you are too busy with your own grievances to think about cutting down his fuel bills. Never say, "It is not my job." If you are wrong, it is inexcusable; if you are right, it is intolerable. Do not do your best to keep your plant running economically only because you fear you may lose your job. Such an engineer should be "fired" at once. The only place for him is in the South Sea Islands, where no one wears clothes and food grows on the trees.—With apologies to Lord Beaverbrook.

The oil should be allowed to stand for an hour or so. Having raised or removed the cover and lagged round the sides of the tank with sackings or any other handy stuff, the resistances should be spaced as symmetrically as possible round the inside of the tank so as to evenly distribute the heat.

Banked In Series

They should be banked in series or parallel according to the pressure available and should be connected to the outside pressure source by means of suitably insulated leads.

Either single phase A. C. or D. C. may be used as the exciting source.

It is necessary to choose the drying out resistance values so as to maintain "Ordinary" oil at a temperature of 175 degs. Fahr. or "Non Sludging" oil at a temperature of 212 degs Fahr. The temperature is taken at the top of the tank.

Although during heating up larger currents may be employed so as to hasten the process it must be remembered that too high a temperature is liable to disintegrate the oil and the heat near the resistance units is the limiting factor.

The average temperature should, however, be maintained at the figures stated, and if the resistance units have to be arranged to pass a higher current than is necessary continuously, it should be applied intermittently.

Readings Essential

During the drying out process the following readings should be frequently taken.

(1) Insulation resistance between H. T. and L. T. windings and between each winding and frame.

(2) Time. (3) Temperature. (4) Power Input.

The process should be divided into three stages, that is:

(1) A preliminary heating up stage of short duration increasing to the maximum. During this period the insulation resistance of the windings falls.

(2) The longer period of drying out at constant temperature. The insulation resistance then becomes practically constant.

(3) A shorter cooling period during which time the insulation resistance increases.

Curves can be plotted of insulation resistance and temperature as ordinates with time as abscissae, such curves giving a graphical indication of the drying out operation.

When the insulation resistance curve commences to rise the moisture may be considered to be removed and the supply to the resistance is cut off. Normal excitation may be applied to the primary side with the secondary windings open circuited in order to dry the core, but on no account should this be done till the windings and oil have been thoroughly dried out.

When Bubbling Ceases

On the cessation of bubbling at the top of the oil, drying out may be considered as effected. The foregoing method has several advantages inasmuch as by drying out the windings, oil and tank at the same time, labor and expense is saved.

The heat being generated at the bottom of the tank where the most moisture is to be found, the maximum temperature is applied where it is most needed, while there is no fear of local heating taking place in the interior of the windings.

With the short circuit method the same preliminary precautions are taken as before. The L. T. winding is then short circuited and low pressure three phase or single phase current applied to the H. T. windings of a value approaching the impedance voltage of the transformer.

The pressure available, if not suitable for application to the H. T. winding, may be applied to the L. T. with the H. T. winding short circuited. Special care, however, must be taken in this case to avoid breakage of the short circuiting connection, otherwise in the event of fracture, high voltage being induced in the H. T. winding, the operator will be in danger.

Temperature should be measured by a thermometer in the oil, preferably a spirit one, and by the resistance of the windings. If the latter cannot be taken, thermometers (spirit ones are essential) should be placed in the vertical oil ducts between the H. T. and L. T. windings.

Gives Heat Formula

If the resistance method is used the temperature corresponding thereto is given by the formula:

$$T = \frac{R(234.5+t)2-34.5\,r}{r}$$

T being the HOT temperature of the windings.
t being the COLD temperature of the windings.
R being the HOT resistance of the windings.
r being the COLD resistance of the windings.
Temperature rise $= T - t$

The value of T should not exceed 212 degs. Fahr.

If a transformer is dried out of its tank, the procedure electrically is the same as described, but the voltage applied must be lower. The transformer should be protected from draught and the steady drying out temperature must not exceed 212 degs. Fahr., when measured by resistance, and 194 degs. Fahr. when measured by thermometer.

If at all possible drying out without oil should be avoided. It has several disadvantages, such as the possible occurrence of local heating in the centre of the windings, and the maximum heat just where it is not wanted.

The transformer and oil having been put into satisfactory condition, the latter if despatched separately can be poured into the tank to the level indicated on the oil gauge.

Oil In Chamber

If expansion chambers are fitted, sufficient oil should be poured in so that at normal temperature there is about 2" of oil in the expansion chamber. The oil should be allowed to stand 6 hours, so as to allow the air therein to disperse. This may be rendered more effective by agitating the oil. External insulators should be cleaned with a dry cloth, and the breather, if supplied, charged with the necessary calcium chloride.

After switching in, it is desirable to leave it on no load as long as possible so that it will become warm from the heat of iron losses which mitigates against the absorption of moisture, assists in the expulsion of air and allows the windings to settle down. When, however, a transformer has to operate in parallel it must be "phased in" before the full primary pressure is applied.

At first it might appear that a transformer would be a piece of apparatus which could well take care of itself, but as a matter of fact intelligent inspection at intervals is well worth while.

It is wise to remove a transformer from its tank every six months, at which time the coils should be tightened up, all nuts examined and a sample of the oil taken from the bottom of the tank and tested for dielectric strength. If sludge has been deposited, the whole of the oil should be run off, filtered and the tank cleaned out. Any moisture tapped at the bottom of the expansion chamber should be drained off, say once a month, and clean dry oil introduced to replace any wet oil taken out.

The breather, if any, should have its supply or drying agent, usually calcium chloride, replaced every week. Periodically the insulators should be wiped down with a dry cloth.

It is necessary to permanently earth, in a direct and positive manner, the tank covers. The core itself should also be well earthed, and it is necessary to make a periodic examination of the paper disc between the electrodes to ascertain if it has deteriorated.

Finally, it is hardly necessary to remind those having access to transformers that to approach the tanks with a naked light when removing the cover is dangerous, the gas generated in the enclosed spaces being sometimes of an explosive nature. —Mayor Johnstone-Taylor.

Convention Notes

The American Society of Mechanical Engineers held their spring meeting in Montreal from May 28 to 31 inclusive. Among the industrial plants inspected by the visitors were the Cedar Rapids Manufacturing and Power Company, the Dominion Engineering Works, the Laurentide Power House and Paper Mill, the plants of the Shawinigan Water & Power Company, and the La Gabelle Power Development.

Julian C. Smith, vice-president and general manager of the Shawinigan Water & Power Company, had prepared a very important paper on "Hydro Electric Possibilities in the Province of Quebec," but was detained in Winnipeg on business and so his assistant, P. S. Gregory, handled it for him.

An explanation of various watershed precipitations in the province preceded the statement that "the potential water-power of the province, due to the precipitation, is about ten per cent. higher per square mile of area than the average potential water-power of the United States." Owing to the present stage of development, under which, in the matter of distribution of hydro-electric power, "only those sites near industrial centres, and at which water-power exists in considerable quantities, are capable of being developed."

In rehearsing the progress of water-power and hydro-electric, it was shown that water power was first developed by the French in Quebec in 1650.

H. R. Naylor, assistant works manager at the Angus Shops of the C.P.R., explained steel car construction at the shops. A description of the machine equipment was followed by an illustration of the method of construction and assembly, which led up to the explanation of the final erection and assembly of the car.

Frederick E. Gaby, of Toronto, chief engineer for the Hydro Electric Company of Ontario, read a paper dealing with the development of hydro-electric plants in Ontario.

Many places of interest were visited, including St. Anne de Beaupre, Mount Royal Park, Art Gallery and the Lachine Rapids. The engineers left Montreal on the night of June 1st.

The Eugenia Electric Association held its annual meeting at Owen Sound on May 30th, and elected officers as follows:—President, John Legate; vice-president, D. Sewall; second vice-president, Dr. Hacking; secretary-treasurer, C. C. Eldridge. Hydro engineers explained proposals for extensions and changes, which received endorsement. A tie line connecting Eugenia with the Niagara system will be built between Harriston and Mount Forest and a second flume will be built at Eugenia, increasing the plant's capacity to 8,000 horsepower.

The Fourth International Congress of Refrigeration will meet in London, England, in June, 1924. This congress was founded by J. de Loverdo, and that it has had such an important bearing on the industry is largely due to the valuable services rendered it by President Andre Labou, former French Minister of Colonies.

Indications are that the 1923 convention of the National Electric Light Association in New York, June 4 to 8, will be the greatest in point of attendance and interest ever held. It is estimated 10,000 members will be on hand.

If the governor belt should break, will your engine stop? If you do not know this to be the case, see to the adjustment of the safety cams on the Corliss engine and to the automatic stops on other types of engines, and make sure that they are adjusted to operate. They are likely to get out of their proper position and should be examined at least once a week, and tested to see if they control the engine.

Boiler Inspection a Joke

BOILER inspection in the province of Ontario is a joke; indeed, many boilers have never had any inspection at all. There is a division of authority by means of which error, responsibility and waste may be shifted around by the minister of labor until it finally rests upon the waste paper basket.

The work at present is under the jurisdiction of two departments of the government—the Factory Inspection Branch whose duty it is to see that factories are provided with adequate machinery guards and sanitary arrangements; and the Steam Boiler Branch charged with the inspection, during construction, of all steam boilers and pressure vessels as well as second hand boilers offered for sale and repairs to boilers to be used later in the province.

It is well known that the province has had and will continue to have able and conscientious service from the Steam Boiler Branch, while alone is sufficient reason for the present absurd system being scrapped and this department given control of all boilers in the province.

A consolidation clearly indicated as the requirement of efficiency and economy.

Solving Coal Problems

THE report of the Dominion Fuel Board for the ten years ending in 1921 which shows that Canada's bill for imported coal in the period investigated exceeded $580,000,000, is more likely to aggravate than to alleviate the coal situation.

Talk of a wider use of British Columbia, Nova Scotia and Alberta coals without offering any solution of the problem of getting such coal to Quebec and Ontario at a price that can compete with American coal, is worse than useless.

The trouble apparently is that everybody at Ottawa is eager and ready to talk ahout what might be done to solve the coal problem but that nobody is doing anything worth while.

If there is danger, as charged, in the present easing in the anthracite supply it should not be beyond the power of the government to solve the transportation problem.

Alberta coal must be carried some 2,000 miles for use in Ontario as compared with the four or five hundred mile haul from the American fields, but if all Canadian railroads were given some form of freight subsidy on coal shipments so as to reduce Sir Henry Thornton's $9 a ton demand to $6 a ton Alberta coal could at least compete with American.

The Fuel Board also urges the use of peat but fails to advise the public where it can be purchased in quantities sufficient to warrant its use.

Such a report serves no purpose except perhaps to advertise the participants. The coal problem is not going to be solved by a declaration of intentions. Surely with all the boards, divisions, commissions and other governmental agencies at work obtaining the facts somebody will do something yet for a change.

* * * *

Simply Chemical Reaction

COMBUSTION is merely a chemical reaction by means of which fuels when combined with oxygen liberate large amounts of heat. The method of combustion which liberates the greatest amount of heat in the smallest volume of clean gas, is the most effective. This means that fuel should be ignited and burned as quickly as possible in order to allow the required proportion of time to bring the hot gasses in contact with the work in hand.

The method of combustion which releases the maximum amount of heat in the smallest volume of carrying medium and increases the time that this hot gas will be kept in contact with the work is the most effective and efficient method.

* * * *

Buy Coal Now

THERE are several reasons which will appeal to every engineer who studies the question, why coal should be bought in the summer months.

One is that there is usually a surplus of bituminous coal in summer and as operators are obliged to keep their mines in operation, there are frequently opportunities for buying up fuel at advantageous prices if it can be stored.

Then there is the fact that the quality of coal on the market in summer is usually better than in fall or winter. This is due to the fact that mining is done under less pressure and greater care is taken in preparing the product.

The cost of unloading frozen coal is another argument in favor of doing as much of this work as possible in summer. The steam required to thaw frozen cars and the extra labor involved add considerably to the cost of coal received in winter.

Depreciation of coal in storage is not a serious matter. No accurate figures have been obtained for the loss of heat units in different parts of the pile but tests have indicated that it is slight.

The cost of handling the stored coal from pile to boiler house usually increases with the amount stored, but the cost of storage equipment becomes less per ton as the quantity is increased.

Each plant requires special study to determine the method best suited to its needs but an investment in coal storing equipment, if wisely made, will rarely be regretted.

* * * *

Beware of Ruts

THE engineer who gets into a rut is likely to get into a ditch. And both are bad things to get into. So, to begin at the beginning, it is well to keep out of a rut. For a rut, if travelled in regularly, becomes a ditch. It is all right to have ideas, and plans, and policies. They cut fuel bills and bring increases in salary. But beware of ruts.

The cure for ruts is variety. The operator of a power plant needs variety every bit as much as three meals a day.

Do the unusual thing. What if it hasn't been done before? Who cares? The engineer must see new things, read new things, hear new things, and have new things.

Gosh! It's tough to do the same old thing day in and day out.

* * * *

It Will Come

THE higher coal goes, the quicker will come a new fuel. It may be oil, or gas, or something else. But it will come.

Whatever the fuel may be, and whenever it may arrive, it is sure to result in changes in power plant methods and, therefore, it is imperative for every engineer to keep fully informed of the latest developments.

Every-day Problems With Answers

Queries are invited on the every-day problems of all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped to solve a problem and a pleasure for us to pass on the data.

THIRD-CLASS CERTIFICATE

What qualifications are necessary to obtain a third-class stationary engineer's certificate, also is one obliged to obtain a fourth-class certificate before a third?—A. Simpson, Brampton.

Answer:—A candidate for third-class certificate shall be required:

(a) To be at least 21 years of age;

(b) To be a holder of a fourth-class Ontario certificate of the current year or its equivalent from one of the other provinces of the Dominion;

(c) To take an affidavit on a form supplied by the Board to the effect that he has had at least two years' experience in a stationary steam or gas plant, showing at least six months' experience in a boiler room and six months' experience in an engine or compressor room;

(d) To pay a fee of five dollars at the time of making application for examination. (This fee shall not be returned to the applicant should he fail to pass the examination);

(e) To answer the questions on the examination paper and secure at least 60 per cent. of the marks.

A candidate for examination for third-class stationary engineers' certificate is required to possess:

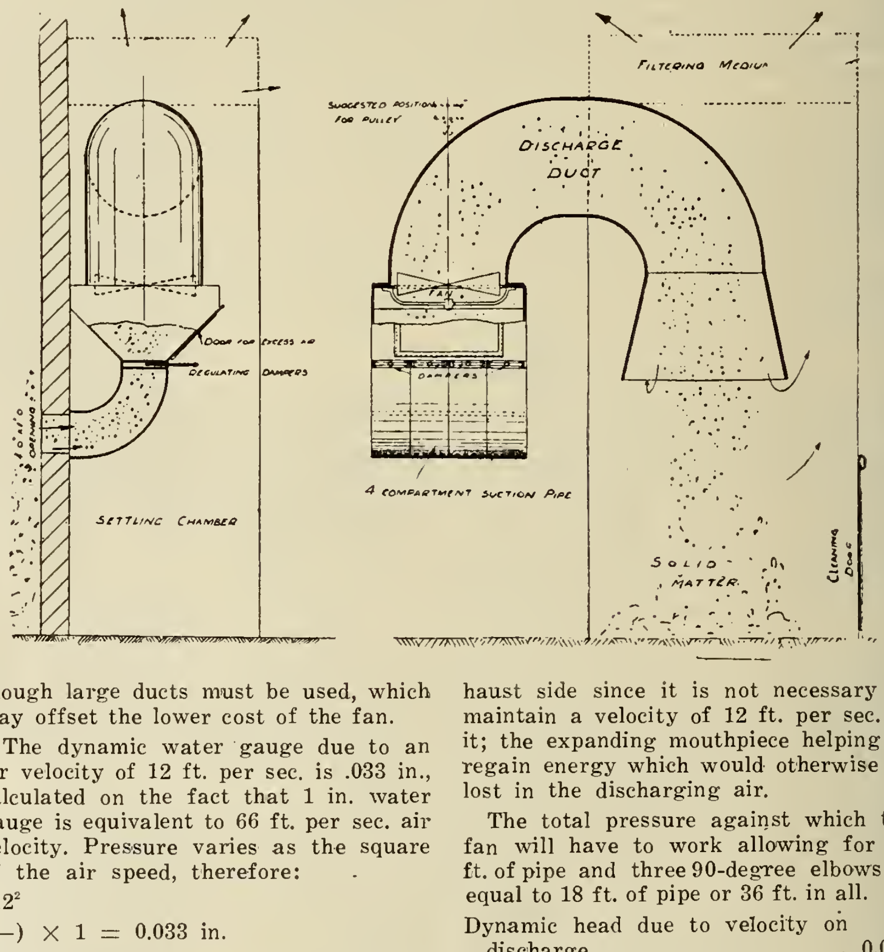
A general and practical knowledge of fuels, combustion, boilers, boiler setting, piping, steam engines, steam turbines, condensors, auxiliaries, electrical equipment, oils, heating and ventilation, hydrostatics, refrigeration, water softening, some arithmetic, and knowledge of injectors, boiler feed pumps, pumps, valves, steam traps, steam separators, reducing valves, expansion joints, lubricators, and any other apparatus commonly used around an ordinary steam plant.

* * * *

TYPE OF FAN

I desire to maintain an air velocity of 12 ft. per second through a vertical stream of material falling across an opening 4 ft. wide by 1 ft. deep. The products to be separated by the air current vary within narrow limits in the air velocity required to float them, but no other satisfactory means of separation presents itself. The velocity of the air across the whole width of the 4-ft. stream of material must be uniform. Efficiencies are of secondary importance. The material to be separated weighs 9 lb. per cubic foot, and an exhausting fan must be used. This material must therefore, be drawn into the fan, and discharged into a settling chamber of ample size to ensure that the fan would deliver at practically atmospheric pressure. I understand that I cannot use any type of fan except a diametral-flow. Kindly give me your opinion of the type of fan.—J. S. M., Vancouver, B. C.

Answer:—The propeller type of fan should be quite suitable for the job, and not as costly as a diametral-flow type although large ducts must be used, which may offset the lower cost of the fan.



The dynamic water gauge due to an air velocity of 12 ft. per sec. is .033 in., calculated on the fact that 1 in. water gauge is equivalent to 66 ft. per sec. air velocity. Pressure varies as the square of the air speed, therefore:

$$\left(\frac{12^2}{66}\right) \times 1 = 0.033 \text{ in.}$$

This is purely dynamic head due to actual air speed, allowance must be made for friction in ducts, bends, etc.

A 30-in. propeller fan of any reliable make should do the work, if fitted up as illustrated, an even flow being maintained by dividing the rectangular suction pipe into compartments, fitting each compartment with a sliding damper, in this case four divisions have been made. The damper can be so regulated to control the air speed over the whole surface of the opening. A propeller fan will not work against a head much exceeding one half an inch water gauge, so small ducts must not be used on the exhaust or the suction side.

The area of a 30-in. fan is 5 sq. ft.; the suction pipe leads into a fan box which is 4 ft. by 2 ft. 9 in. The total air to be handled over the area with an air velocity of 12 ft. per sec. is 12 × 60 × 4 × 2.75 = 7,920 cu. ft. per min.

A 3-ft. diameter pipe would do in the exhaust side since it is not necessary to maintain a velocity of 12 ft. per sec. in it; the expanding mouthpiece helping to regain energy which would otherwise be lost in the discharging air.

The total pressure against which the fan will have to work allowing for 18 ft. of pipe and three 90-degree elbows is equal to 18 ft. of pipe or 36 ft. in all.

Dynamic head due to velocity on discharge	0.08
Static loss in duct system	0.279
Resistance through filter, say	0.15
Total inches of water-gauge	0.509

BOILER PLATES

What is the thinnest plate that may be used in power boilers?—R. S. M., London.

Answer.—According to the A.S.M.E. code (revised 1923) the minimum thickness of any plate under pressure shall be ¼ in. The minimum thickness of plate in stayed surface construction shall be 5/16 in. These safety factors are also the minimum allowed by the Canadian Interprovincial Regulations.

* * * *

STEAM FOR STOKERS

How much steam is required to drive underfeed stokers and fans?—L. T. J., Windsor.

Answer.—The amount of steam required to drive underfeed stokers varies with the type and method of drive. Mechanically driven stokers are claimed by the makers to use less steam than other types. From 2 per cent. to as high as 5 per cent. of the steam produced may be used in driving the stokers and the fans for forced draft.

* * * *

CORRECT POWER FACTOR

What is the most convenient method to correct the power factor in a plant which has several large induction motors?

Answer:—Induction motors cause low power factor due to a lagging current. Power factor with induction motors may be improved by loading the motors to the full rated load. If this is not possible and the power factor must be improved, part of the load should be taken by synchronous motor with an over excited field causing a leading current which counteracts the lagging current of the induction motor, thus helping towards unity power factor.

* * * *

STEAM VELOCITY

What velocities should be used in pipe lines with superheated steam and what are the advantages of high velocities?

Answer:—The usual velocities for saturated steam 3,000 to 6,000 ft. per min., may be greatly exceeded with superheated steam since there is no moisture present to cause water-hammer. For high steam pressures 10,000 to 12,000 ft. per min. is advisable for lines over 5 inches in diameter, with a continuous steam flow as for instance when used in turbines. 12,000 to 15,000 ft. per min. can be and have been used in larger pipe lines without any trouble. The pressure drop with superheated steam is much less than with saturated, due to its lower density, the absence of moisture, the dry pipe walls and the reduced amount of foreign matter. Higher velocities may be used, resulting in smaller pipe lines for the same capacity.

The use of smaller pipe lines also cuts down the radiation losses. A chemical company had an 8 inch pipe line 1,400 ft. long in the plant conveying steam from the boiler room to a process house. An increase in production required double the amount of steam, a second pipe line was planned. Superheaters were installed in the boilers after which it was found that the old pipe line would carry all the steam necessary, the radiation losses per pound of steam being decreased 36 per cent.

DUPLEX PUMPS

In a direct acting duplex pump, if one piston bumped at the right hand end of its stroke and ran short at the left end, how would you correct it?

How many thousands of an inch small must a ring be bored which is to be shrunk on the 8-inch diameter boss of a flywheel when heated to 500 F. in a workshop temperature of 60 deg. F?

Answer:—The striking of the piston at one end of its stroke and running short at the other is a result of faulty setting of the valves. On all duplex pumps there is an adjustment provided, with some on the linkages which operate the valves, on other pumps by means of the lock-nuts on the valve proper.

To reset the valves of a duplex pump locate the steam piston in the centre of the cylinder. This can be accomplished by pushing the piston to one end of its stroke against the cylinder and marking the rod with a scriber at the face of the stuffing box, and then bringing the piston in contact with the opposite end, and again marking with the scriber.

Divide exactly the distance between the two marks on the rod, then shove the piston back to this mark, bringing it in the centre of the steam cylinder.

Perform the same operation with the other side of the pump, then place both slide valves in their central positions, passing each valve stem through the stuffing box and gland. Locating the pistons in the centres of their cylinders brings the levers and the rock shafts in a vertical position. Next screw the valve stem through the nuts until the hole in the eye of the valve stem comes in line with the hole in the links, connecting the rocker shaft, then put the pins in their places and adjust the nuts on both sides of the lugs, leaving about one-eighth to one fourth of an inch lost motion on each side.

Answering the second part of your question and assuming that the ring is of mild steel and that it is to be heated from 60 deg. F. to 500 deg. F. With the co-efficient of expansion for steel as .000,006 the diameter on heating would increase .000,006 x 8 x 440 = .021 of an inch. To allow for the slight cooling of the ring when fitting to the boss, it should not be bored more than .016 of an inch smaller than the boss.

* * * *

STOPPING COMPRESSORS

How would you stop a compressor?

Answer:—First close the main expansion valve and keep the machine running until the back pressure drops to about 2 pounds, then close the throttle on engine and shut the machine down. Close oil valve and stop valves on suction and discharge lines; then shut the cooling water off the condensers and compressor cylinder.

* * * *

REFRIGERATION

How would you start a compressor?

Answer:—First start the cooling water on the compressor cylinder and condenser, then open the valves on compressor discharge line and the oil valve. Next gradually open the engine throttle until the machine is at its proper speed. After the first few revolutions, the stop valve on the suction line is opened gradually. When the suction valve has been open full and the back pressure reduced to about 10 pounds, the expansion valve is opened slightly, allowing some of the charge to go over. When the charge is about right and the expansion valve properly adjusted, the secondary expansion valves on each of the coils should be adjusted until each of the coils frost alike. The back pressure to be carried varies with different machines from 15 to 25 pounds and is determined by the marner in which the outlet from the expansion coils frosts back.

* * * *

HOW GAS TRAVELS

Explain how the gas travels from the discharge to the suction of a compressor.

Answer:—Through the discharge line to the oil trap, from the oil trap to the condensers; where it is cooled and liquefied. It is now a liquid and drains into the receiver and on to the expansion valve. It is controlled through the expansion valve and passes through the evaporating coils, absorbing the heat from the surrounding space or brine; it passes out of the coils through the scale trap and to the suction of the compressor.

Antifriction metals, so called, are useful for lining bearings chiefly because of the ease with which they can be forced (poured) and their ability to permit crushing and abrasion without great increase in friction, not because they have a lower co-efficient of friction, hence antrifriction is a misnomer.

If the polarity of a generator becomes reversed, it may be corrected by lifting the brushes clear of the commutator, opening the circuit-breaker and shunting its terminals with small fuse wire. Then close the main switch for a few seconds and the generator fields will become energized in the right direction from the busbars. Before opening the main switch, however, it is well to cut in the field-rheostat resistance.

The Graver Corporation, East Chicago, are circulating a booklet dealing with the employment of waste steam in the treatment of water for purposes of softening. Various curves are given for the general conditions occurring in feed water together with the beneficent effects to be obtained by the application of heat to the softening process. The publication is comprehensive and clear.

Babbitt metal should not be used over and over again for the reason that every time babbitt metal is melted some of the tin and antimony is burned out.

Practical Ideas From Practical Men

TREATING COILS

Having read the article by W. McKenzie on page 34 of the May 5th "Power House," perhaps a description of the process used by a large electrical manufacturing company to treat motor and dynamo coils with a varnish or compound, might be of interest to readers.

After the coils have been wound with cambric and tape which has been properly treated, they are placed in a large tank with a removable cover that can be made air tight. With the coils in the tank and the bolts of the cover tightened up, a vacuum pump is operated for half an hour or so, so as to form a vacuum inside the tank, as well as to extract any air which may be collected in the coils. The valve on the air pipe is then closed, and another valve opened which permits a varnish or compound to be drawn by the vacuum into the tank.

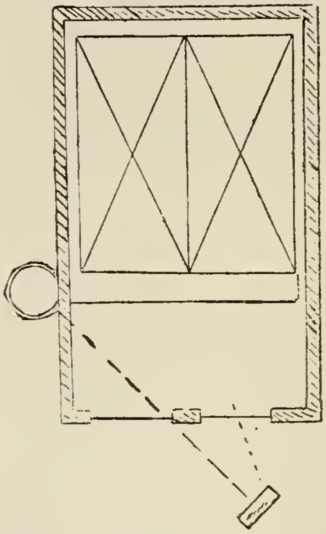
The apparatus is so arranged that it is known when enough varnish or compound has entered the tank to cover the coils. The compound valve is then closed and a valve on a pipe from air compressor is opened and an air pressure of 90 pounds placed on top of the compound. It is obvious that it is impossible for any space not filled with compound to exist in the coils. What the vacuum does not draw in the pressures forces in. Before the air pressure is cut off the compound is blown out of the coil tank into a receiving tank so as to be ready for the next batch of coils, the connecting valve is closed, the air pressure cut off, the pressure in the coil tank allowed to drop, the top removed, and the coils taken out and baked as described by Mr. McKenzie. —JAMES E. NOBLE.

MIRROR A SAVING

While the little kink of using a mirror placed in such a position as to make it convenient for the fireman to watch the condition of his smokestack is not a new one—in fact 'is a very old one—it is worthy of repetition because of the limited extent to which engineers in general have availed themselves of it.

Perhaps no other feature of power plant operation offers as great possibilities for saving as does that of firing and combustion, and one of the factors entering into this is the matter of smoke, usually one that is overlooked because the man doing the firing is unable to tell just what conditions he is producing in the way of smoke.

This mirror arrangement, installed so that it reflects the image of the stack top, usually makes it possible for the fireman to note the effect of his firing on the smoke, and all without leaving his post in front of the boilers, and this little kink is therefore strongly recommended for use in those plants where a serious attempt is made for improvement along these lines. The same idea, of course, can be used in watching the exhaust from atmospheric relief lines, vent lines from receivers, etc.



LEAKING WATER

A 300 h. p. iron tube closed heater commenced to leak badly, installed in a location where it was impossible to make any repairs on it unless considerable equipment was removed. The heater was supplied by a cold water feed pump which forced the water to the boiler, thus the heater was always under boiler pressure.

A second pump was installed between the heater and the boiler, acting as a boiler feed pump, the cold water pump then serving only to supply the heater. A ¼ inch pipe 16 feet high was placed on a high joint on the discharge from the heater, to assist in keeping the heater under atmospheric pressure. A pressure gauge was also placed on top of the heater.

By adjusting the speed of the two pumps by hand control of the valves it was found to be an easy matter to keep approximately atmospheric pressure on the heater, resulting in very slight leakage of the heater.

D. R. McNally, Callender, Ont.

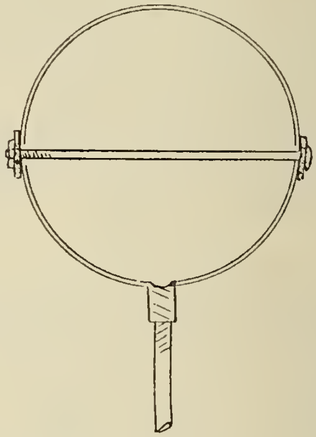
LUBRICATOR TROUBLE

A lubricator with a bull's eye sight feed glass persisted in cracking. It was found when replacing the glass that if a thin mica disc was placed on the inner side of the glass and the packing nuts tightened, the trouble from breakage ended. The mica can be readily cut with shears or a sharp knife.

D. R. McNally, Callender, Ont.

REPAIRING A FLOAT

Probably no other thing in the power house gets cussed as much or as frequently as floats—those used in a multitude of capacities about the plant, mostly in connection with control valves of various kinds. They seem to leak with almost unfailing regularity, and seem to resist equally well most attempts to repair them by soldering, etc. We recently ran into a case where a 6-inch diameter round float on our make-up tank valve sprang a leak, and for three successive Sundays we had it out for repairs, but each time the hole could not be effectively plugged with soldering methods. In desperation our repair man, who apparently was anxious to get at least one Sunday off, rigged up a cure as shown in the attached sketch, which seems to have done the trick. He accomplished it by putting another hole in the float opposite from the original one, and then putting through a long narrow specially made bolt, which served to pull together a packing ring around each hole. This float, fixed in this manner, has now held up for three months, and perhaps some other engineers will want to try it on one of their hopeless cases of float leakage.



INCREASES LIFE OF BRUSH

The usual life of brushes can be greatly increased by placing fibre discs between the brush and the spring, in order to maintain sufficient pressure of the brushes on the commutator. When buying new brushes engineers should make sure that the pig-tails or other connectors will allow the brush to be worn till it is thin. With some types of connections a brush three inches long when new may have to be discarded when not more than one half of the brush has been worn out; with others it can be worn down to less than ½ inch thick.

The brush holders should be adjusted so that the brushes wear evenly on both sides. In our plant we place fibre discs between the brushes and the springs and thus are able to wear them down to about ¼ inch; the softest brush gives the best service, as well as being the easiest on the commutator.

A little care given to brushes and commutator will save considerabie money in a short time.—JOHN DAVIS.

TIGHT STEAM JOINTS

To make tight steam joints, take white lead ground in oil, incorporate as much manganese (black oxide) as possible, adding a small portion of litharge. Knead it with the hand, dusting the board with red lead. The mass is made into a small roll, and laid on the plate, first rolling the plate with linseed oil. It then can be screwed and pressed into position.

Power Notes

The report that the American Radiator Co. was negotiating for the purchase of the Dominion Radiator Co., Toronto, has been confirmed by the New York office of the former. The current rumor to the effect that the purchase price would approximate $2,000,000, is incorrect. It is expected that details of the merger will be made known in a few days.

The Canadian Power Co. is building at Niagara Falls, an outdoor transformer station. This will cost approximately $150,000 and when completed will have a capacity of 60,000 horsepower.

The Imperial Oil, Ltd., have let the contract for the building of their new plant at Owen Sound to Schultz & Co., Brantford, and work will be commenced shortly. There will be a number of separate buildings, including office, warehouse, pump-house, stables and garage. Two large storage tanks and two shipping tanks will also be erected. The buildings, etc., will cost in the neighborhood of $70,000.

Ratepayers of Thornbury, Ont., recently endorsed a by-law for issuance of debentures to construct and install a waterworks system. The by-law provides for the construction of a pump-house, filter, water tank and pumping machinery. The town is utilizing its own electric energy.

Sealed tenders will be received by Fred B. James, Walkerton, Ont., to Monday, June 18th, 1923, for the following works at the County Buildings, Walkerton, for the Bruce County Council; the erection of addition to County Council building; the erection of central heating building and trenches for pipes, and the installation of central heating plant.

G. A. Maguire, salesman, has resigned from Canadian Tube and Steel Products, Ltd., it is claimed, to organize a company for the purpose of manufacturing wrought iron pipe. It is understood the new concern will operate under the name of Tube Products, Ltd., in a plant on the old Dominion Shipyard property at foot of Bathurst Street, Toronto, for which a lease has already been granted by the Harbor Commission. A new process of manufacture, it is claimed, is the chief stimulating influence behind this project. It is said that a process for the manufacture of seamless wrought iron pipe was recently submitted by a Toronto inventor to the United States Steel Corporation, but according to H. C. Scholfield, vice-president of Page Hersey Tubes, Ltd., no purchase or agreement materialized.

Premier Greenfield and Attorney-General Brownlee, of Alberta, who have been in Ottawa in consultation with the house committee on mines and minerals, regarding the coal situation in Canada, spent a few days in Toronto before returning to the West.

City Engineer McFaul, of Hamilton, Ont., in accordance with instructions from the board of control, has prepared a report on the method of installing a chlorinating plant at the pumping station. Duplicate apparatus would have to be installed, and the plant would cost in the vicinity of $8,500.

Peterborough Utilities Commission has accepted the tender of the Canadian General Electric Co., of that city, for switching equipment for the new electrical distribution station there. The amount of the contract accepted is $30,745. Only one other Canadian firm tendered for this equipment, and that was the Westinghouse Co., whose tender totalled $36,460.

John Inglis Co., Toronto, are at present working on an order for fifty heaters for the Worthington Pump Co., and expect to have the order completed in another two weeks' time.

Sealed tenders will be received until 12 o'clock noon, June 8th, 1923, by E. L. Ruddy, chairman of building committee, 317 Spadina Avenue, Toronto, for boiler house, concrete pipe conduits, chimney, boilers, piping, auxiliary equipment, radiation and domestic hot water equipment for the Toronto Free Hospital for Consumptives, Weston, Ont. Plans and specifications may be seen at the office of the consulting engineer, Melvern F. Thomas, 229 College Street, Toronto.

The Westinghouse Electric & Manufacturing Company have been given the contract to electrify 213 miles of its track by the Virginian Railway. The order includes construction of electric locomotives, power house, transformer station and apparatus, and the total expenditure will be $15,000,000.

Kirkland Lake, Ont., is expending approximately $150,000 in installing waterworks.

The Quebec Streams Commission and the Quebec Development Company, Limited, have filed plans at Ottawa relative to the water power project in the Lake St. John and Chicoutimi district. The cost of this work will be over $20,000,000.

The Public Service Corporation and the Q. R. L. H. & P. Co., of Quebec, P. Q., have amalgamated and will be known in future as the "Quebec Power Company, Limited."

The Bawden Machine Co., 163 Sterling Rd., Toronto, are installing a complete waterworks pumping station of the township of York at the village of Oriole. The equipment includes Sterling and Kermath Engines as an auxiliary to the electrical power.

W. S. Haggas, for some years with H. W. Petrie, Limited, Toronto, has been appointed Canadian representative of the Keighley Gas & Oil Engine Co., Keighley, England. Mr. Haggas has opened an office in the Petrie Bldg., 131 Front St., W. The Keighley Company produce engines ranging from 5 to 600 h. p. adapted to industrial, municipal waterworks or power plant requirements.

The John T. Hepburn Co., Toronto, are installing in the new Morgan Bldg., Montreal, pumps for the purpose of supplying high pressure steam to electrical generating plants. Two of these pumps are 11 x 14 x 20 in. to be used as vitalizers, which are designed to serve 70,000 square feet of direct radiation. Two other pumps are of the horizontal ram type—12½ x 9 x 12 in. for boiler feed purposes. Another installation which the Hepburn people are making is that of a 4-stage centrifugal pump with a capacity of 150 Imperial gallons per minute against a total head of 600 feet. This equipment will be installed in Lynn-Canyon as an auxiliary waterworks plant for the district of North Vancouver, B. C.

To keep in touch with the operation of the plant to determine if it is working at the highest efficiency, it is necessary that a correct log be kept of all departments. This log of itself has no value unless it is carefully analyzed from day to day to determine whether the plant did maintain the highest efficiency on each particular day under the conditions at which it was necessary to operate.

Cylinder oil containing fatty acids should be avoided, as it is apt to injure the metal. The acid absorbed by the piston and valve-rod packing sometimes attacks the rods, when the engine is out of service, to a serious extent.

Rosin oil is cheap and its specific gravity high, therefore it is sometimes used to adulterate lubricating oil. When it has been considerably refined, it can be added in large quantities without much chance of detection except by a chemist; but since it has no lubricating qualities, the action of the mixture will be unsatisfactory.

Progress in New Power Equipment

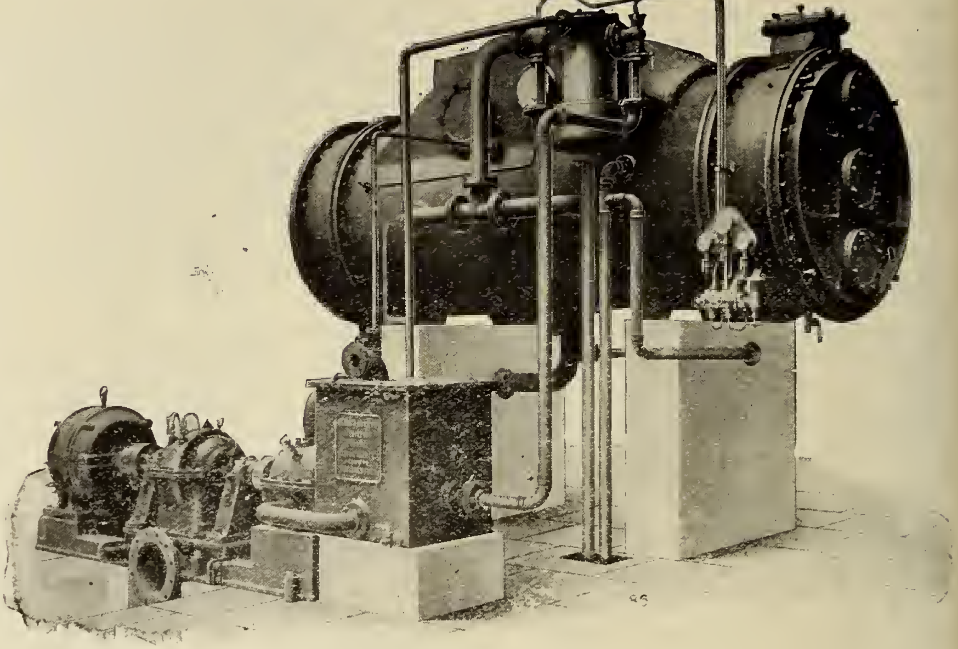


Figure One.

CONDENSING PLANT TYPES

There are two main types of condensing plants, surface and jet. The surface is possibly the more popular, but in many instances the hard nature of the condensing water supply precludes its use owing to the inevitable scale formation on the inside of the tubes. It is then necessary that direct contact should take place between the steam and the condensing water in a jet condenser.

Since the advent of the steam turbine great strides have been made in condensing plant design, especially in that of the surface condenser.

Laboratory experiments in universities, and trials on a larger scale on manufacturers' test plates have enabled the problem of heat transmission from the exhaust steam to the condensing water to be more fully investigated.

The general principles of surface condenser designs are now fairly well established, but the main value of the experimental data obtained is that it has formed a basis upon which can be made a proper comparison and valuation of results given under ordinary running conditions.

Results Aid Designer

From these latter results the designer has been able to acquire knowledge of the essential correction factor for formulae founded upon laboratory and test house trials.

The surface condensing plant illustrated by Figure 1, represents an up-to-date design, and has been evolved from considerable past experience. This experience applies not only to the manufacture of the plant but also to questions arising in connection with its installation.

This is a matter of equal importance for in every instance a thorough investigation of individual conditions and requirements must be made if all-round success is to be attained.

The condenser has a cast iron body and water ends, with brass tube and tube plates, and internal baffles, ensuring the passage of the steam over the whole condensing surface and eliminating any "dead" spaces. There is, however, but little obstruction to the free flow of steam inlet and the air pump outlet.

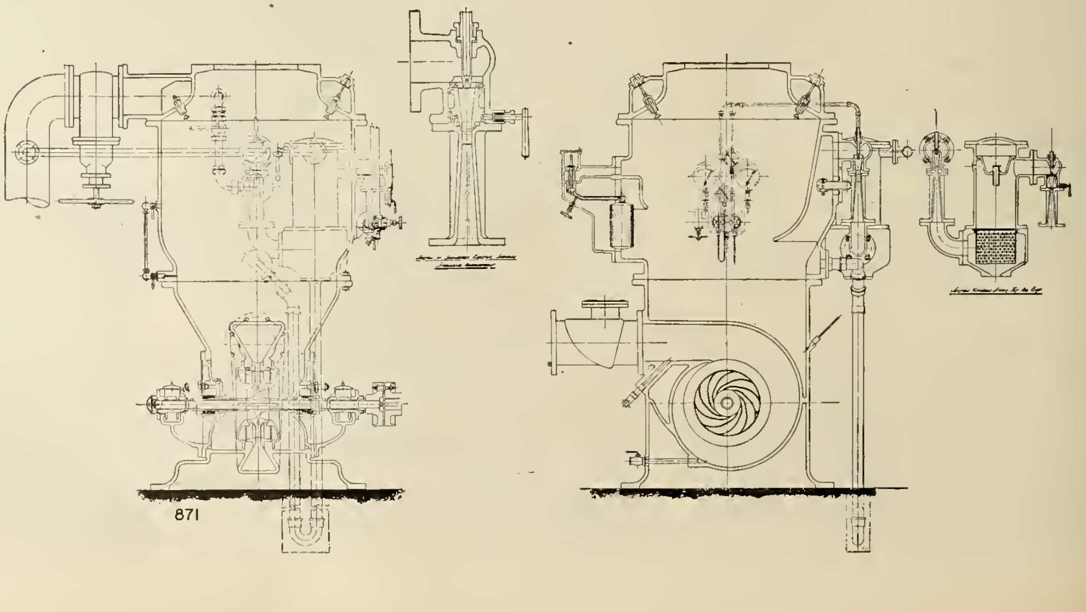
The velocity of water flow through the tubes is between 4 to 6 feet per second, depending upon various factors, and is sufficient to keep the tubes free from any matter carried in suspension with the water, and further tends to reduce scale formation.

The problem of air extraction from a vacuum chamber has been attacked in various ways but the simplest and most direct of them all is that of steam jet extraction. Further, it is one that gives good efficiency, for the steam passed through the air extractor can be afterwards wholly or in part utilized for heating the boiler feed, thus maintaining the thermal balance.

The surface plant illustrated is equipped with an air extractor of this type, being of the two-stage with intermediate condensation design. It is of the utmost simplicity in construction and very reliable and economical in operation.

The difficulty of stabilization of the

Figure Three—Sectional Drawing of Typical Multi-Jet Condensing Plant.



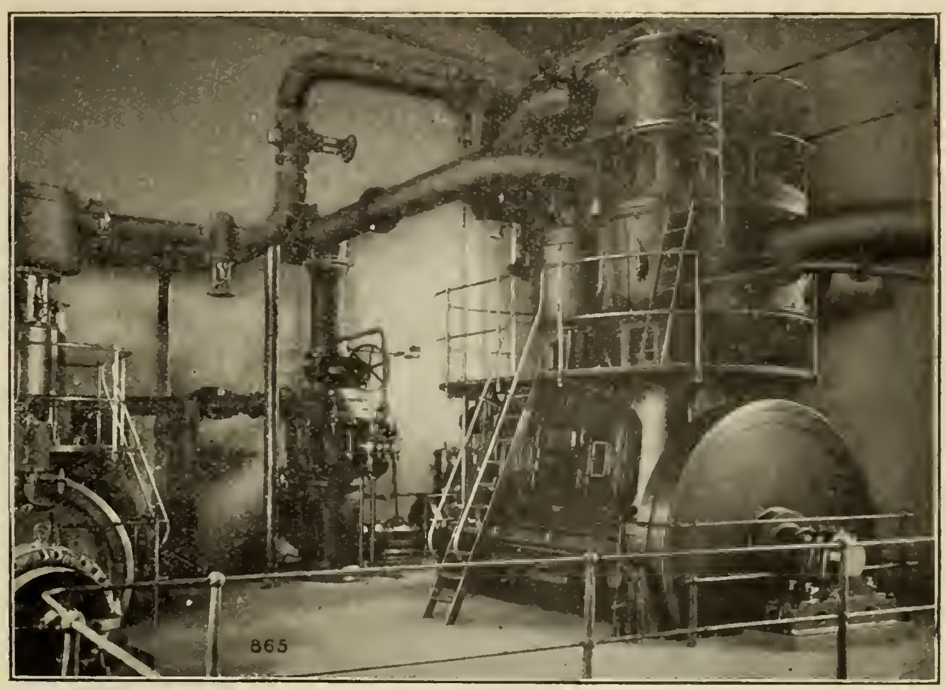


Figure Four.

jet over a large range of vacuum readings has been overcome in a quite satisfactory manner by returning again through the final ejector throat a portion of the discharged vapors. Thus stabilization is attained without the use of excess air.

The circulating water pump and condensate pump are of the centrifugal type, the latter pump delivering into a tank, receiving also the steam discharged from the final air ejector, thus conserving its heat value. In the same body as the condensate pump is a second disc which delivers the condensate from the tank to the boiler hot well.

Driven by One Motor

The pumps are arranged for driving by one motor and the whole forms a compact and easily handled plant, equally applicable to turbine or engine duty.

The jet condenser is the oldest form of all condensing plants, but it is only within recent years that much effort has been expended on improving its efficiency and design. The earlier plants employed reciprocating pumps to remove the contents of the condenser, dealing with both the air and water, and as the latter is of considerable volume the pumps were cumbersome and costly.

The newer method adopted is to extract the water and uncondensable vapors separately, the water being dealt with by a centrifugal pump, which can remove the large water quantity involved with a pump of very much smaller dimensions than those of a corresponding reciprocating pump, and moreover, with very much less cost for upkeep and renewal.

Removes Air Efficiently

The removal of the air from the jet condenser is effected on modern plants most efficiently by a steam ejector air pump of exactly the same design as that already described for use on a surface condenser. Thus standardization of air pump is obtained for either type of plant, with all the inherent advantages of quick and cheap production.

Figure 2 illustrates a multi-jet condensing plant and Figure 3 is a sectional drawing of a slightly larger size.

The exhaust steam inlet is at the top of the condenser through an unobstructed passage into the condensing chamber, and is there met on the whole of its circumference by the condensing water, leaving special spraying nozzles which effect an intimate mixture between the steam and the water.

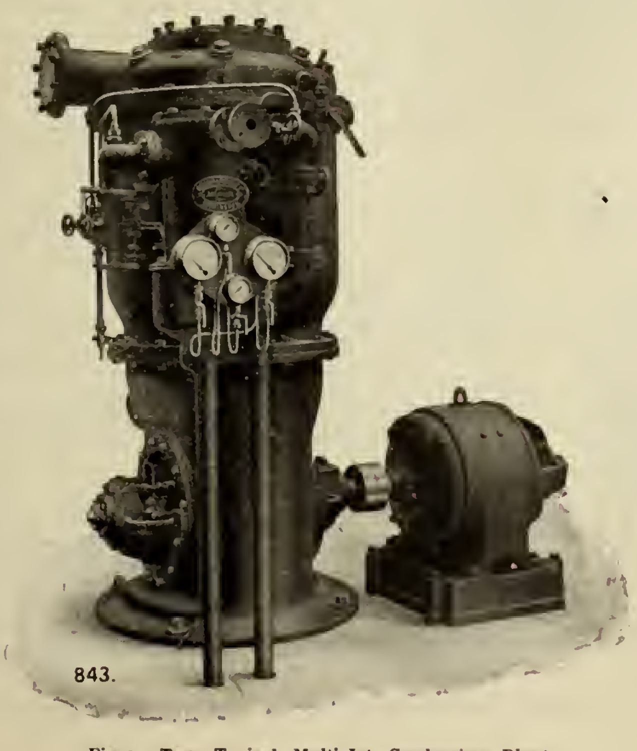

Figure Two—Typical Multi-Jet Condensing Plant.

The heated water falls to the bottom of the condenser to be dealt with by the centrifugal extraction pump, and the non-condensable vapors flow into a passage through a spray of cold water to the first stage of the air extractor.

It will be noted that the water extraction pump forms the base of the condenser, thus saving floor space, also by the directions of the connection between pump impeller and water chamber overcoming many of the difficulties experienced on the suction side of a centrifugal pump drawing from a high vacuum.

The whole of the internal parts of the pump are accessible through the side cover, and the shaft bearings are exterior to the pump, thus allowing of oil ring lubrication and the maintenance of the bearing in a close state of adjustment.

Impeller Design Special

The design of the impeller is special to meet the unusual conditions on the suction side, which demand special consideration and accuracy of manufacture. The material of the impeller is hard gunmetal; the shaft is of high-grade steel fitted with hard gunmetal sleeves where it passes through the water-sealed stuffing boxes.

In addition to the other usual accessories the condenser is fitted with a vacuum breaker, which comes into action should the water level rise too much above the normal, and a non-return valve is provided for the water discharge branch, thus rendering the plant quite safe in operation.

As in the case of the surface plant previously described this multi-jet plant is suitable for turbine or engine duty and Belliss & Morcom, of Birmingham, England, the manufacturers, report that samples of both types are in full commission and giving every satisfaction to the users.

Fig. 4 shows a multi-jet condensing jet plant receiving the exhaust steam from a 5,000 cu. ft. steam-driven compressor. Notwithstanding the comparatively small size of the condenser, it has given perfect satisfaction in operation and maintains a good vacuum. Incidentally, it may be mentioned that at the time the photograph was taken the plant was in full operation.

DIFFERENTIAL RELAY

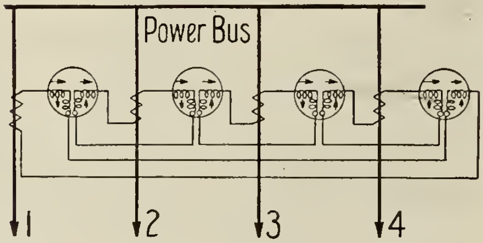
A current relay that requires no more apparatus or connections than ordinarily needed for the simple overload (short circuit) protection of transmission lines has been developed by the Westinghouse Electric and Manufacturing Company, for giving balanced protection to transmission lines. Where two or more transmission lines are in parallel between generating stations or sub-stations means must be provided for disconnecting a defective line without interrupting the power service in the remaining lines. Various methods of accomplishing this are in common use, but practically all of them involve the use of special apparatus.

This relay works on the induction principle and operates on current alone, so that no source of potential is required. This is a very great advantage, particularly on high voltage lines where the cost of potential transformers is considerable. Also there are no phase relations to be considered in connecting up this relay.

Simple Construction

The relay has two overload elements acting upon a common disc through a common magnetic circuit. Each element is connected separately to its own current transformer in corresponding phases of the two balanced lines. The two elements are electrically opposed, and under conditions of balanced line loads the fluxes in the magnetic circuit of the relay are equal and opposite, giving a resultant zero torque on the relay disc.

Under these conditions the disc which carries the moving contact is held in a mid-position by the control springs. These springs are initially restrained in the zero position, which prevents the disc from making any movement until a predetermined current unbalance exists between the two lines. Under the proper condition of current unbalance the disc can rotate 80 degrees in either direction from zero and make contact on either side. Thus the moving contact acts as a single pole, double-throw switch in the trip circuits of the circuit breakers of the two unbalanced lines, and will trip out the circuit breaker on the line carrying the heavier load. This action is the same regardless of the relative directions of the currents in the two lines.



Method of Application.

Differential Current

The differential current which is required to trip the relay is practically the same for all load values of line current in the lower loaded line. If, however, one line of the balanced pair is open, the current in the relay necessary to cause it to trip out the remaining line is approximately twice the differential current setting. This automatic doubling of the current setting with one line open is due to the fact that half of the operating coil of the relay is then no longer active, as it receives no current from the dead current transformer in the open line.

This is a very desirable feature, as it gives automatic protection to the service if one line is accidentally opened. Thus if each line were carrying 100 per cent. load, with the relay set to operate at a differential current of 150 per cent. of the load of one line, and an accidental switching operation occurred to open one end of one of the lines, the remaining line would carry the double load.

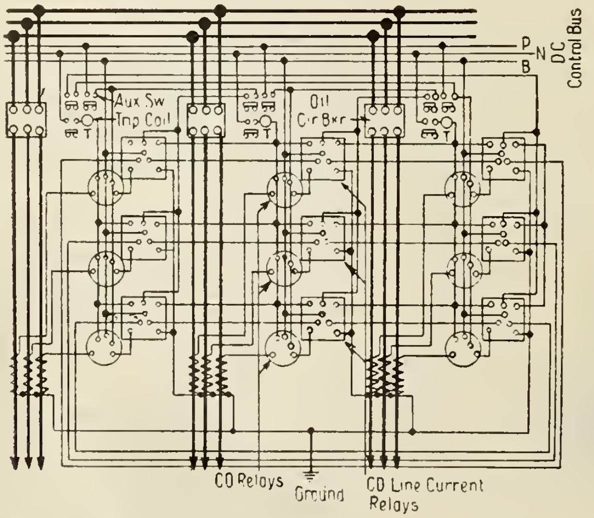
The relay on the opposite end would not, however, close contacts due to the unbalanced load current for, although, the one line would then be carrying 200 per cent. load, the relay setting would have been automatically increased to 300 per cent. leaving an ample margin of safety. When the accidentally opened switch was closed, the balanced protection would be again restored. This feature also makes it unnecessary to render the trip circuit of the differential relay non-automatic while the parallel lines are being connected to the busses at both ends; for it can be seen that after both ends of No. 1 line, and one end of No. 2 line have been closed, the same condition will exist as described above when one end of one line is accidentally opened.

Automatically Converted

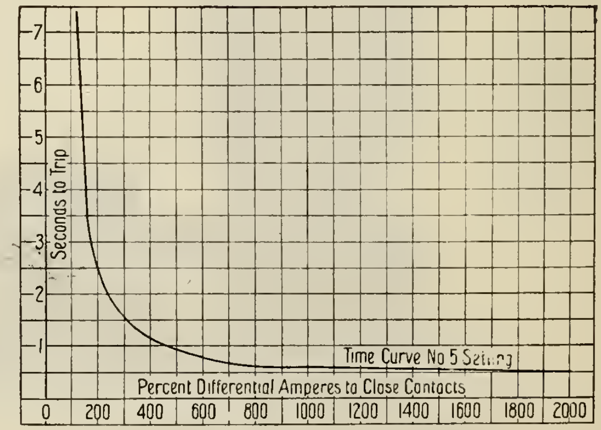
It will be noted that when one of the lines is opened the differential relay is then automatically converted into an overload relay, with a tripping current setting of twice the differential setting, and with the disc tending to rotate in such a direction as to trip out the loaded line. This means that the remaining line may then be considered as provided with overload protection without the use of additional overload relays, if so desired.

It should be remembered, however, that the current balance relay is set for a short time operation, which is not usually desirable for overload protection.

The condition of through short-circuits, i.e., short-circuits on other sections of the system, should also be considered, as this condition usually requires selective settings of the overload relays in series on the system. For this reason it is customary to use overload relays in series with the current balance relays to give selective overload protection to the remaining line after one



Connections for Protection of Three Lines.



Load-Time Curve Showing Adjustable Minimum.

Babcock & Wilcox Chain Grate Stoker

For Natural Draft

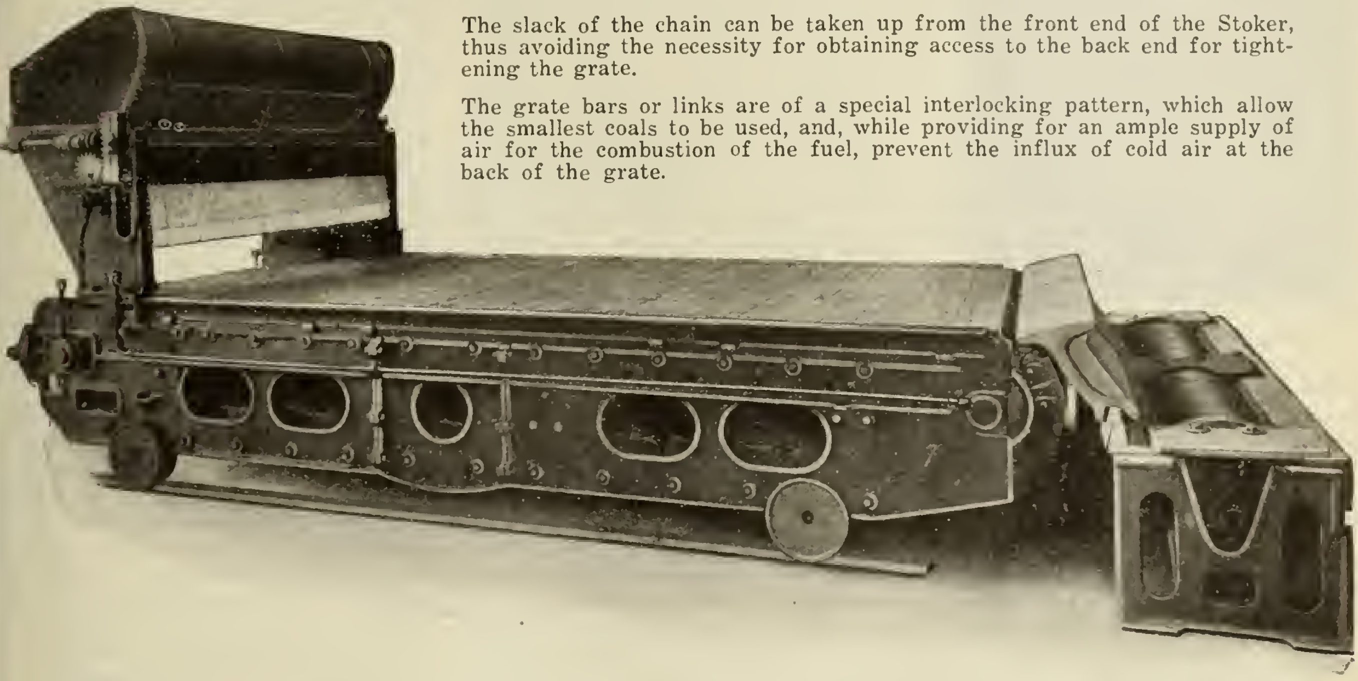
The grate consists of an endless chain of short interlocking cast-iron grate bars, linked together, running on angle irons and rollers and driven by a revolving shaft and sprocket wheels at the front end of the Stoker. The necessary power to drive the revolving drum is transmitted through a link chain and sprocket wheels from a shaft arranged either overhead or underground.

The starting or stopping of the Stoker, or the variation of speed, is effected through the B. & W. patent gear box, which can be driven at varying speeds. This box forms an oil bath in which the gear runs, and also contains an efficient clutch for putting the driving gear out of action should any unusual strain arise from an obstruction on the grate.

Any small repair, such as replacing a link, can be carried out with the Stoker in place under the boiler; but in case of need the whole Stoker can be brought out clear of the boiler, the frames being provided with wheels running on rails placed at the sides of the ashpit.

The slack of the chain can be taken up from the front end of the Stoker, thus avoiding the necessity for obtaining access to the back end for tightening the grate.

The grate bars or links are of a special interlocking pattern, which allow the smallest coals to be used, and, while providing for an ample supply of air for the combustion of the fuel, prevent the influx of cold air at the back of the grate.



The coal is fed over the whole width of the grate, and the depth of the fire is regulated by the adjustment of the vertically lifting fire door.

THE FEED OF THE COAL IS SLOW and the gas evolved from the fresh fuel as it drops on to the grate readily perfects its combustion by passing over the incandescent fuel further on.

The depth of the fire being regulated by a vertically lifting fire door, the Stoker CAN BE ADJUSTED IN A MOMENT to suit the class of fuel to be consumed and varying demands for steam, both by the depth of the fire and the speed of the grate.

The Stoker is easily manipulated and so simple that any fireman can understand it. It is the only form of stoker in which the undue admission of air at the back of the grate is prevented and with it THE HIGHEST EFFICIENCY is obtained.

The Stoker ultimately proves itself the embodiment of economy because it is efficient and saves coal over any other method of firing and the cost of upkeep is low compared with any other type.

The first cost of some other makes may be less, but consideration must be given to whether they have the necessary metal in them to stand up under the work they are intended to do. By reducing the weight of metal the price can be lowered but only at the sacrifice of the durability, consequently the cost of repairs will be great. Due consideration should also be given to whether by any other method of firing the price of the Stoker can be recovered in the amount of coal saved in a given period.

Full information given on request.

BABCOCK & WILCOX, Limited

HEAD OFFICE FOR CANADA - COLLEGE ST. (ST. HENRY), MONTREAL

TORONTO OFFICE: BANK OF HAMILTON BUILDING

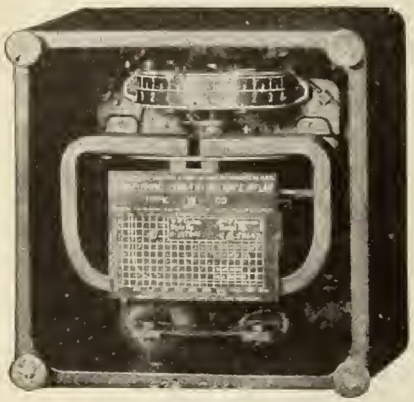
of the balanced lines has been disconnected.

Differential Settings

Differential current settings of 3, 4, 5, and 7 amperes, are provided. The relay has an inverse time curve, with a definite minimum time of operation, adjustable from instantaneous to 0.5 second.

The current balance relay can be used at the transmitting ends of any number of parallel feeders. It can be used at the receiving ends of any number of parallel lines in a system having a source of power at both ends, or at the receiving ends of three or more parallel lines in a radial system.

In brief, it can be applied at any point in a system where, in case of trouble on one parallel line, this line will receive more current than the other line of the pair. An ideal application of current balance relays is for the protection of parallel tie lines between generating stations.



Relay With Cover

Lines Not Identical

It is sometimes the case that parallel lines are not identical in characteristics, such as being different sizes of wire, or of different lengths of line. In this case the current balance relays can be used for protection by creating equal currents in the two elements of the relay by the use of balancing auto transformers to step-up the current of the low line. The loads of the two lines must, however, be proportional at all times.

The current balance relay can also be used for the ground protection of parallel transmission lines. The neutral currents of the two lines are then balanced against each other and in case of a ground on one line the predominance of current will be in the neutral of the grounded line. The ground relays are identical with the line relays except that they operate on lower differential current values.

An engine runs forward or over when, standing at the cylinder and looking toward the flywheel, the wheel revolves in a direction away from you.

MANY UNIQUE FEATURES IN THIS NEW AIR COMPRESSOR

A new line of steam driven air or gas compressors ranging in size from 67 to 1083 cu. ft. piston displacement per minute has recently been placed on the market by the Canadian Ingersoll-Rand Company Limited, 260 St. James St., Montreal, Canada.

These machines, known as the Class "FR-1" are the steam driven companions of this company's Class "ER-1" belt-driven compressors and like the latter are of the single stage, straight line centre crank dust and dirt proof type with automatic lubrication of both running parts and compressing end.

They embody every refinement of modern compressor design including a number of features which make them as nearly automatic in action as any machine of this type can be expected to be. This is an important consideration in any compressor but is even more essential in the case of small and medium sized units which are often operated in isolated locations where but little attention can be given them. Large machines on the other hand are generally located in a central power house under the supervision of an expert engineer. For this reason the Class "FR-1" compressors are suitable for use in small mines, quarries, on contract jobs, in foundries, machine shops, industrial plants, etc., as well as for use as auxiliaries in large air power plants.

In general the Class "FR-1" compressor consists of a plate valved compressing cylinder direct-connected to steam engine with balanced piston valve and automatic cut-off control, a design which makes it possible to operate with high pressure and super-heated steam as well as the moderate pressures more common in the past. This feature alone ensures a steam economy at all pressures not heretofore attainable.

The main frame is of the enclosed type, the bottom part forming a reservoir for the combined splash and flood lubrication system. It is fitted with removable side and crank end covers, which are not bolted on, but are retained by lips on the frame casting. Removal of these covers permits inspection or adjustment of all running parts. The cross-head guides are of the bored type and the design of the frame provides for an oil stuffing box near the cylinder end of the frame, which prevents any chance of crank case oil entering the compressing cylinder end of the main frame and in the trunk piece interposed between the steam and air cylinders provides for adjustment of all stuffing boxes when the machine is running.

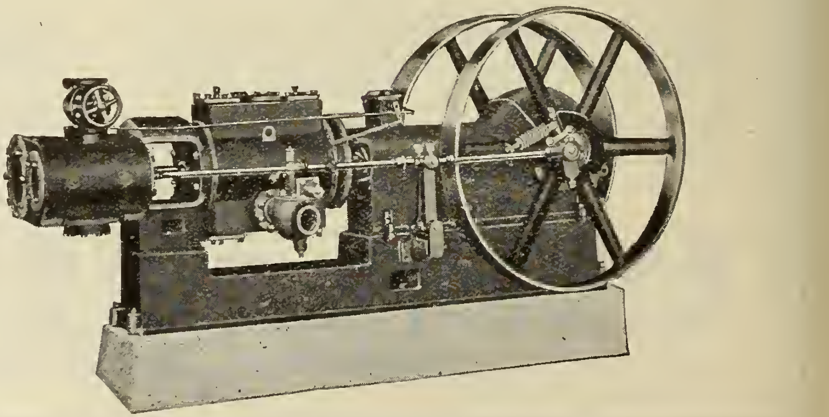
The main frame and trunk piece are mounted on a substantial cast iron subbase which lends rigidity to the entire structure, makes the machine a complete self-contained, accurately aligned unit and also forms a support for the single rocker arm which guides the valve rod. There are no guide blocks or other sliding surfaces in the piston valve gear.

The main bearings are of very heavy construction and are provided with removable die-cast shells or liners of genuine babbitt metal which can be removed and renewed in a few seconds at small cost. Due to the area of the bearings and the complete circulation of oil through them at all times, however, the shells last for very long periods without appreciable wear.

The crank-shaft and connecting rods are solid one-piece drop forgings accurately machined and heat-treated. The connecting rod is of the solid end type with renewable and adjustable boxes in both cross head and crank shaft ends. The cross-head is of the cylindrical type, of box construction with adjustable bored and turned shoes. Pistons are of the box type with broad faces and are securely fastened to a turned and ground steel rod.

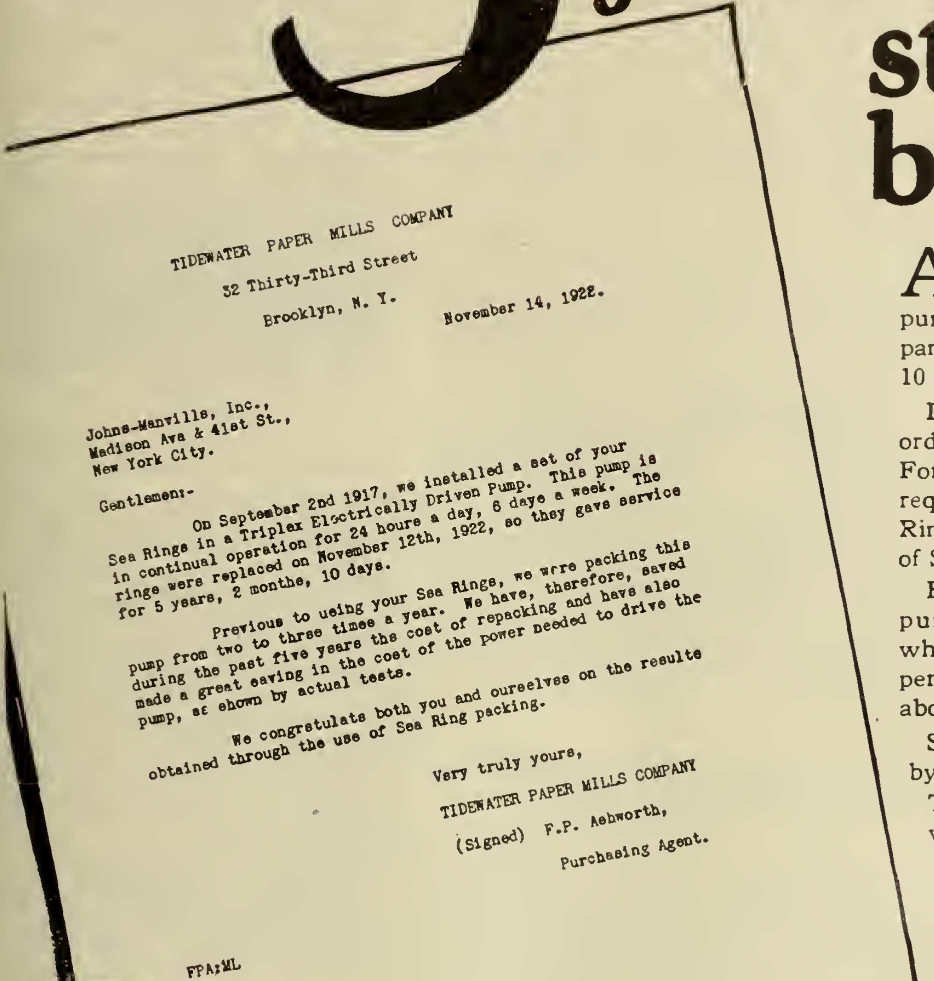
Oil is distributed to all of the running parts by throwers on the crank webs which lift or throw the oil against baffles from which it runs to all wearing surfaces. Lubrication of steam and compressing cylinders is provided for by a double compartment adjustable sight feed mechanically operated lubricator.

The piston valve is provided with two piston rings at each end and operates in a renewable bushing. With this type of valve there is no rapid wearing or cutting and the valve chest stuffing box is only subjected to exhaust pressure as steam is admitted to the centre of the valve and exhausted from the ends.



Compressor with wide range automatic cut-off governors.

Again! 5 years in the stuffing box!



TIDEWATER PAPER MILLS COMPANY
32 Thirty-Third Street
Brooklyn, N. Y.
November 14, 1922.

Johns-Manville, Inc.,
Madison Ave & 41st St.,
New York City.

Gentlemen:-

On September 2nd 1917, we installed a set of your Sea Rings in a Triplex Electrically Driven Pump. This pump is in continual operation for 24 hours a day, 6 days a week. The rings were replaced on November 12th, 1922, so they gave service for 5 years, 2 months, 10 days.

Previous to using your Sea Rings, we were packing this pump from two to three times a year. We have, therefore, saved during the past five years the cost of repacking and have also made a great saving in the cost of the power needed to drive the pump, as shown by actual tests.

We congratulate both you and ourselves on the results obtained through the use of Sea Ring packing.

Very truly yours,
TIDEWATER PAPER MILLS COMPANY
(Signed) F.P. Ashworth,
Purchasing Agent.

FPA:ML

A SET of Sea Rings installed on an electrically driven triplex pump at the Tidewater Paper Company's Plant lasted 5 years, 2 months, 10 days.

It cost $20 to pack the pump with ordinary packing lasting 5 months. For 5 years 12 packings would be required, total cost $240. The Sea Rings cost about $115—a net saving of $125.

By actual *wattmeter* test, the pump ran with 23.3% less power when packed with Sea Rings—at 1c per K. W. H. the Sea Rings saved about $850 worth of power.

Saving in packing and power cost by Sea Rings totals $975.

The amount saved by Sea Rings varies according to conditions. But one thing is certain—Sea Rings average a far greater economy than any other rod and plunger packing.

CANADIAN JOHNS-MANVILLE CO., Limited

Toronto Montreal Winnipeg
Vancouver Ottawa

JOHNS-MANVILLE
Power Plant Materials

The Sea Ring is a scientifically constructed rod and plunger packing. Cylinder pressure trapped in the U-shaped section forces the packing against the rod or plunger just in proportion to the tendency to leakage. This automatic action cuts friction, saves power and increases the packing life.

Regulation of Class "FR-1" Compressors is regularly provided for by an Ingersoll-Rand "Wide Range" Automatic Cut-off Flywheel Governor and either "A-39" Inlet or the new Ingersoll-Rand "Free Air Unloader."

Announcements

200 H. P. Goldie and McCulloch Co. water tube boiler and a Combustion Engineering Co. type E single retort underfeed stoker, are being installed at the plant of the Northern Aluminum Co., Toronto.

The John Hepburn Co., Toronto, recently shipped to East Vancouver, B. C., a four stage 150 gal. per min., 600 ft. head, centrifugal pump for the Water Works Dept.

Canadian Non-Exhaust Pneumatic Machine Co., Ltd., has recently been incorporated with a capital of $750,000, to manufacture machinery, boilers, compressors, pumps, etc. The head office will be at Kingston, Ontario.

The St. John Hydro Commission has recommended to the city council the acceptance of a tender by the Stephen Construction Co., of that city, for the civic hydro distribution system. The figure is $63,745.

T. M. Grindley Company is now the name of the organization handling the sale of the products of the Conveyors Corporation of America in the Province of British Columbia. The address of the Grindley Company is 1158 Homer Street, Vancouver, B. C.

The Grindley Company was the western office of Gormans Limited, Edmonton, and operated under that name up to May 1, but after that date, T. M. Grindley took over the business, organized his own company and enlarged his selling staff.

Mr. Grindley has associated with him in the new firm J. H. Sinclair, a sales engineer of experience who has been in the west for some years and latterly has been representing the Aurora Pump Company in Ontario as well as being sales manager for the London Concrete Machinery Co., of London, Ont.

The Northern Canada Power Company have let contracts to proceed with the development of a first unit of 20,000 hydro-electric horsepower at Des. Quinze. The firm of Morrow & Beatty has been awarded the contract to build the plant, and Sutcliffe & Neelands, together with Gordon Summers have been engaged to survey the transmission line.

The Winnipeg Hydro-Electric system has decided to install a steam stand-by plant, using two 5,000 K.W. condensing and one 1,000 K. W. non-condensing steam turbines. The steam is to be furnished by three 1,100 h.p. Erie city type vertical water tube boilers, which are being built and supplied by the John Inglis Co., Limited, Toronto.

For The New Ford Plant at Ford, Ont., the Combustion Engineering Corporation are making good progress in the installation of a fuel pulverizing plant which will be equipped with three 1,000-horsepower units. Three McAleenan boilers are being installed.

In December, 1922, James B. Duke, of New York, and Sir William Price, president of Price Brothers & Company, Ltd., of Quebec, incorporated the Quebec Development Company for the development of 1,200,000 h. p. to be generated by the construction of a great dam at the head of the Saguenay River in Quebec.

British Trade generally keeps improving, despite disputes brewing in the industrial, shipping, and railway world. Iron and steel prices reached a peak in April. The week ending April 14 saw record coal shipments. Production reached 5,776,600 tons. Fifteen vessels, aggregating 51,531 tons, were launched by Clyde builders during the month.

Price Brothers will erect two new mills in which part of this power will be used, and existing mills will be converted to the use of electric power. The contract for the electrical machinery to be used for generating this power was awarded the Canadian Westinghouse Company, Hamilton, Ont. This order includes eight hydro-electric generators rated at 30,000 kv-a each at 80 per cent. power factor, generating 13,200 volts, 3-phase, 60-cycle at 112½ r.p.m. These generators are of the vertical shaft type and are equipped with Kingsbury thrust bearings. A direct connected exciter with a capacity of 225 kw. at 250 volts will be supplied with each generator.

PRODUCTION AND POSSIBILITIES OF LIGNITE CHAR

(Continued from page 29)

The combustion zone can be maintained by burning some of the distilled gases within the moving mass of lignite, and such direct heating is more efficient than where heat must be transmitted through refractory walls. The hot gases of combustion also pass through the mass, driving off the moisture and departing fairly cool. It is something like an open-top lime kiln. The process has proved simple and efficient. Of the gas driven off, much of it is used in the combustion zone, and in addition, less than 5 per cent. of the weight of the original lignite is burned. That is to say, the fixed-carbon loss in the process of drying and distilling is lower than is usually found for drying alone where separate driers are used.

Passing the combustion zone the lignite enters a lower section protected from the air, where it cools and is then removed. The char obtained by such a process may, of course, be briquetted.

In February about 100 tons of Saskatchewan lignite was tried, to discover whether it presented any special problems.

About two and a half tons of raw lignite reduce to one ton of char, and the heating value is about 12,000 B. t. u. per lb. The moisture is very low, and the char can be stored without danger of fire or degradation in size. Where the freight charge is heavy it would be an advantage to ship char instead of raw lignite.

STEAM TURBINE COSTS

(Continued from page 27)

Automatically, therefore, more high pressure steam is available for prime movers. At the same time, the additional steam into the condenser system helps to raise the feed water temperature, thereby helping to decrease the amount of "bleeder" steam necessary, and, of course, saving high pressure steam.

It might be said that the "bleeder" valve floats on the line and acts as an automatic heat balance regulator. Hence the same heat balance effect is obtained as in the combination motor-turbine drive. The first cost of the unit is lower than that of the combination unit, while the automatic feature alone pays a big return in the time saved to the operating engineer.

Turbine Ideal Drive

It seems reasonable that auxiliaries in the boiler room should, for the most part, be steam driven. The average power plant is made up of two component parts; first, the boiler room, which delivers energy to the generator; and second, the generator, which turns that energy into electricity and feeds it to lines. Therefore, is it not logical that the boiler room should depend on its own steam for operation so that it will always be ready to furnish steam for generating purposes?

The moment the generator shuts down for any reason, the boiler room immediately becomes incapacitated. If it is operating at the time, on an electrically driven boiler feed pump or induced fan, these immediately become disabled and the operating engineer must be able to fall back upon the steam drive.

If we settle in our own minds the fact that the steam drive is reliable in the boiler room, then we can pass on to the question of the type of machine which should utilize the steam.

Trade Catalogs

F. G. Sterne & Sons, of Brantford, are the publishers of a series of booklets which should be of great interest to all who are interested in the operation of boilers. The most comprehensive of these books is entitled "Boiler Scale, Its Prevention and Removal," and deals with the elimination of this boiler room nuisance by the use of silicate of soda. The passage of water through a boiler is dealt with most thoroughly, attention being paid to all of the factors which enter the field. Attractively put together, this book should prove of value to all stationary engineers.

CLASSIFIED ADVERTISEMENTS

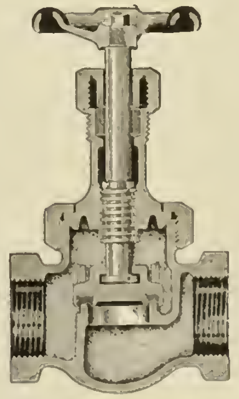
PRATT & CADY VALVES



It is real economy to install Pratt & Cady Bronze Union Bonnet Renewable Disc globe and angle valves. It is so easy to replace parts subject to wear that you are sure to take advantage of this feature.

P. & C. Folder No. 2 describes this valve in detail. May we send you a copy?

This furnace has not been relined in four years!

AFTER so much trouble with ordinary brick linings at the Otis Bldg., Chicago, that, as the chief says, "we did not know whether we were keeping up steam on coal or brick," they relined with

PLIBRICO
JOINTLESS
FURNACE LINING

This was four years ago. The linings under the four Edge Moor Boilers, have never been replaced. The chief says, "they promise a lot more service."

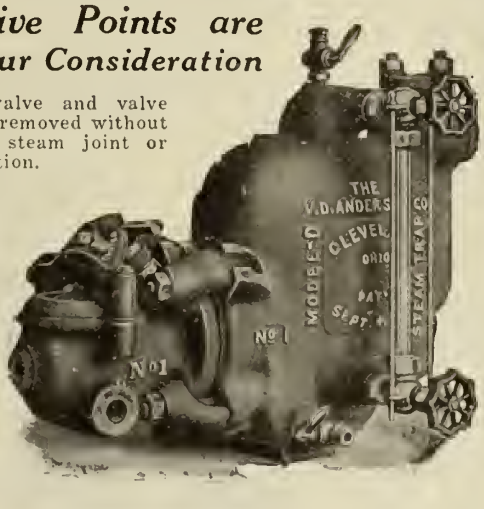
Plibrico is a plastic lining applied with mallet and trowel. When baked, it forms a jointless lining—airtight, gastight, resistant to temperature of 3100 deg. F.

Ask for the 50 page booklet. See 'phone books for warehouses in 52 principal cities. *Plibrico is delivered only in steel containers of distinctive appearance as shown below.*

JOINTLESS FIRE BRICK Co
1142 CLAY ST., CHICAGO, ILL.

ANDERSON MODEL "D" STEAM TRAP

These Five Points are Worth Your Consideration



1. Both the valve and valve seat can be removed without breaking a steam joint or pipe connection.
2. The valve is always sealed with at least three inches of water, making the escape of live steam impossible. The strainer and sediment chamber prevent sediment or scale getting into the valve.
3. A glass water gauge fitted to the trap makes it possible to ascertain at a glance whether the trap is working properly.
4. Made for high or low pressure or exhaust steam. Will lift water against back pressure 5 lbs. less than pressure of trap.
5. Built of best possible materials for the purpose. Every part interchangeable.

THE V.D. ANDERSON CO.
1935 West 96th St. Cleveland, Ohio

Can a Barrel be Emptied through the Bunghole as quickly as it can be filled through the Open Head?

Seems like a foolish question. Yet this is the principle on which most steam traps are designed—with an opening of only ¼ inch in the discharge valve while the pipe connection has a 1½ inch hole. And then you wonder why you require such a large, expensive trap to handle your condensation.

It's different with the American Ideal. Here the valve discharge orifice is much larger than in ordinary traps.

As a result, the American has a larger discharge capacity at the different pressures than any other trap having the same size inlet. Consequently you can use a smaller trap of the American Ideal **continuous flow type** than of other makes.

AMERICAN
IDEAL STEAM TRAP

is the only trap with a powerful enough leverage to operate a valve with such a large orifice.

Because of this powerful leverage, we can use a heavy float, of **thicker, stronger,** seamless copper, which will withstand a pressure of 600 pounds to the square inch. This heavier float eliminates the danger of the float collapsing and enables us to guarantee it for the life of the trap.

These features, and others like the reversible and renewable Monel metal valve stem, renewable phosphor bronze seat, water sealed valve, etc., make the American Ideal the most efficient and durable as well as the cheapest trap on the market.

Write for interesting booklet R-33.

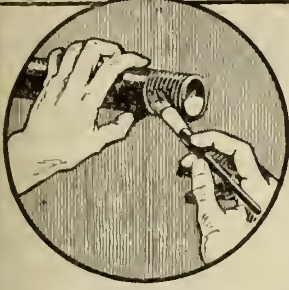
Make tight screw-thread joints with
SMOOTH-ON "No. 3"



JUST BRUSH IT ON THREADS

Make Your Screw-thread Joints with SMOOTH-ON "NO. 3"

As one engineer said, "I make all my screw-thread joints with SMOOTH-ON 'No. 3' and every joint made that way is one less thing to worry about!"

And that's a fact! SMOOTH-ON "No. 3" will make screw thread joints permanently and everlastingly tight. Vibration, heat, cold and violent temperature changes have no effect on SMOOTH-ON "No. 3."

Our Instruction Book No. 19 should be in the hands of every Engineer. It contains valuable facts on power plant installation, maintenance and repairs that are drawn from the actual experience of 77 Engineers. Send for it—it's FREE—a post card will do.

SMOOTH-ON Cement "No. 3" comes in paste form, ready to use and is sold by Supply Houses in 1-lb., 5-lb., and 10-lb. tins.

SONDERGLASS

"The Unbreakable Boiler Gauge Glass"

Two Glass Tubes in One

The different metals used allow for expansion and changes of temperature to which the glass is subjected, and add greatly to its pressure-resisting qualities, as each of these metals has different degrees of expansion. The inside of the tube expands in proportion to the temperature of the steam or hot water and the outside according to the temperature of the air.

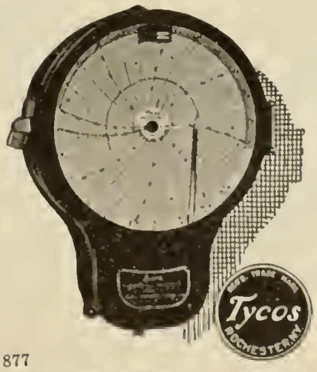
Tycos and **Steam Pressure**

On long steam lines the problem of pressure is an important one. *Tycos* Recording Pressure Gauges are placed at each end of the line. Any drop or rise in pressure is found simply by comparing the two charts. The charts show the time of fluctuations enabling the operator to more easily seek out the cause. Pressure leaks are detected by the recorder at the far end of the steam line.



Have you a copy of our Power Plant Catalog? Write for a copy to-day.

UNION PIPE COUPLINGS

Are Positively Non-corrosive at the Joints

Your dealer has them. Manufactured by Dart Union Company, Limited, Toronto

Building a one-piece furnace lining without special forms.

BETSON'S
REG. U.S. TRADE MARK PAT. OFF.
PLASTIC FIRE BRICK

Makes practicable, solid, one-piece furnace linings, including front and back arches, side walls and baffles. It costs but little to install in any make or type of boiler. It saves fuel, annoying shut-downs, costly repairs, and increases the amount of power from the fuel used.
Complete details of the many uses, methods of installing, how to order, measurement blanks, etc., are contained in a booklet of information which we will gladly send you. Tell us the individual to whom it should be addressed.

Emergencies Prove Its Superiority

It may not be often that the oil film fails in any of your bearings, but the possibility is always present. It is emergencies such as this that test the value of your bearing metals. Magnolia Anti-Friction Metal protects your shafts and bearings from damage in such temporary contingencies. With the lowest frictional coefficient of any known bearing metal proven by U.S. and foreign government tests it runs cool with less lubricant and is a safeguard against hot boxes and melting out where lubrication is neglected or may fail for any reason.

Try out a sample Magnolia-lined bearing and test its many advantages for yourself.

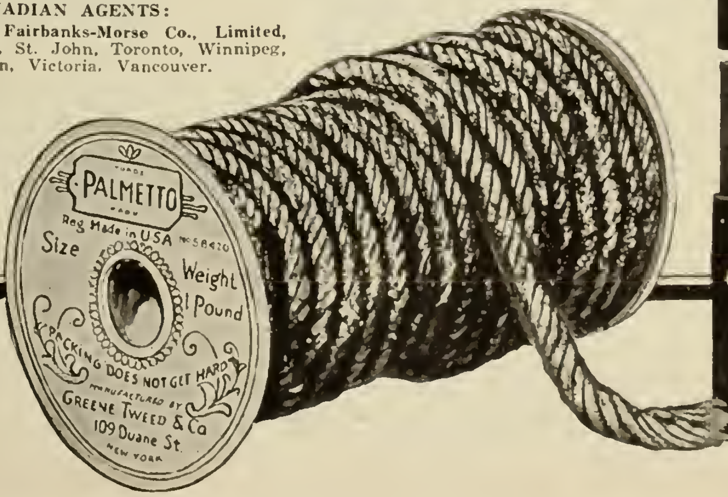
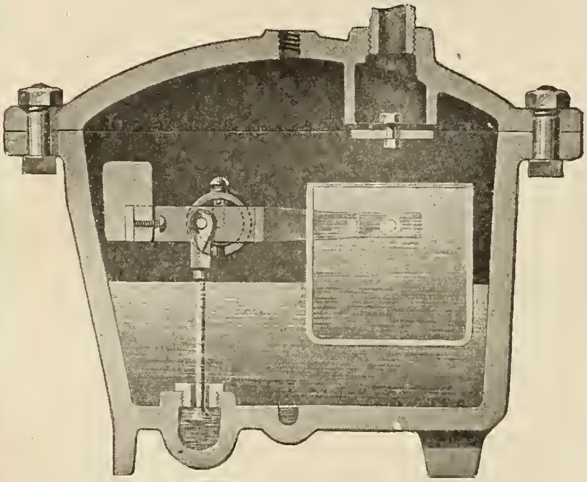
Twist for Valves



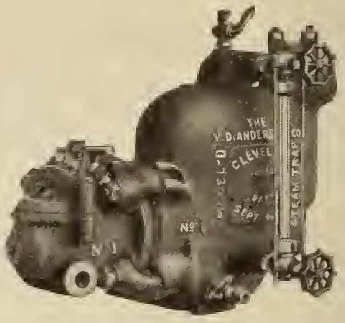
MORRISON
STEAM TRAPS

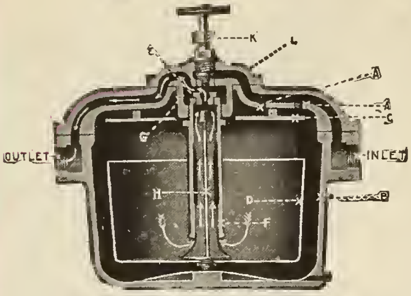
Keep Your Pipe Lines Free From Condensation



Universal Steam Trap—Works on any pressure from ½ lb. to 150 lbs. per square inch. Does away with the necessity for ordering Traps to suit certain pressures.

Anderson Model "D" Steam Trap—Made for high or low pressure of exhaust steam. Lifts water against back pressure 5 lbs. less than pressure of trap. The valve is always sealed with at least three inches of water, making the escape of live steam impossible.

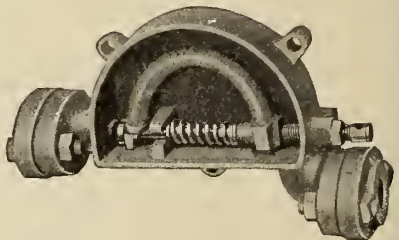




SECTIONAL VIEW.

Outside View

"Nason" Steam Traps receive and automatically discharge the condensation from heating surfaces of every description, without loss of pressure or waste of steam. Made to suit various pressures from 1 lb. to 150 lbs. All parts interchangeable.



Haines Steam Trap — Starts wide open. Is compact, needs no attention and can be installed in inaccessible places. Will not freeze.

POWER HOUSE

Fostering Economy in the Development of Power for All Industries

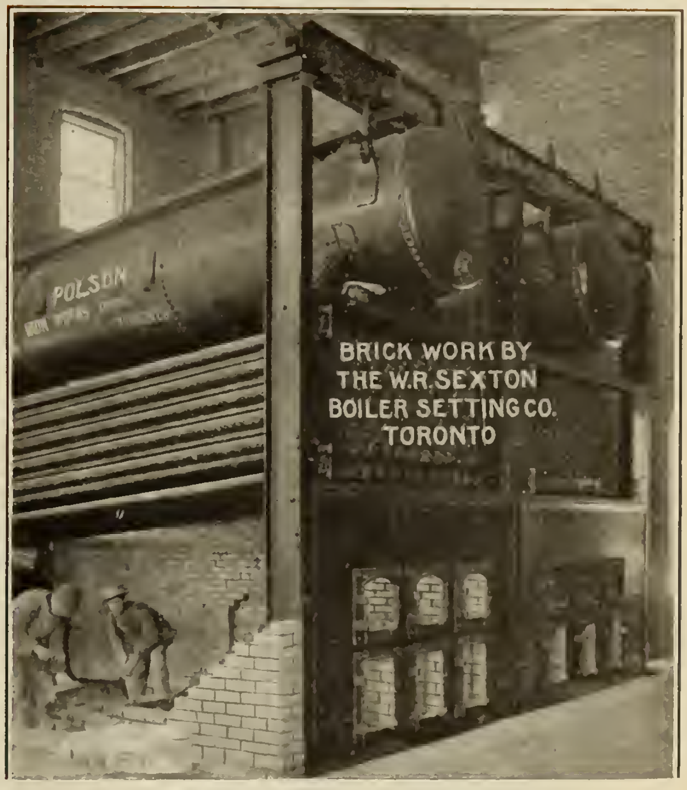
Vol. XVI—No. 12. Published Semi-Monthly by The MacLean Publishing Company, Limited, Toronto, Ont. June 20, 1923

Welcome, C.A.S.E. Delegates

Let
"Safety-First" Sexton
Handle Your
FIREBRICK WORK

You can't be too particular about your Firebrick work. There's no two ways about a job of that kind—it's got to be done RIGHT.

That's why some of the most important plants in Toronto make a point of having all their Firebrick work done by SEXTON. They appreciate the work of a specialist in Firebrick work of all kinds; they know that SEXTON has built up a reputation for doing his work thoroughly, whether it is building-in boilers or just general repairs; they know that SEXTON Boiler Settings last longer and are 100% EFFICIENT and SAFE.



Only the best High Tension Fire Cement is used by SEXTON in his Firebrick work.

"BURN ALL" NONPAREIL GRATES

A Child Can Operate It

save you money right from the start. At a conservative estimate they are saving 10% on fuel bills for many leading Canadian plants. Even with low-grade fuel, NONPAREIL Shaking and Dumping GRATES ensure maximum heat value. The 65% air space and 95% underdraft—a feature of NONPAREILS under perfect working conditions—gets the last bit of heat from the last bit of fuel.

Let us tell you about our 30-day trial—it will interest you.

AGENTS: W. Green, Church St., Smiths Falls, Ont. Gates Engineering Co., Montreal, Que. Mr. A. McTaggart, Leamington, Ont.

THE W. R. SEXTON BOILER SETTING CO.

Established 1900 114 Grenadier Road, Toronto Phone Junc. 2765w

Renewals and Repairs for all kinds of Shaking and Dumping Grates for all sizes of Boilers.

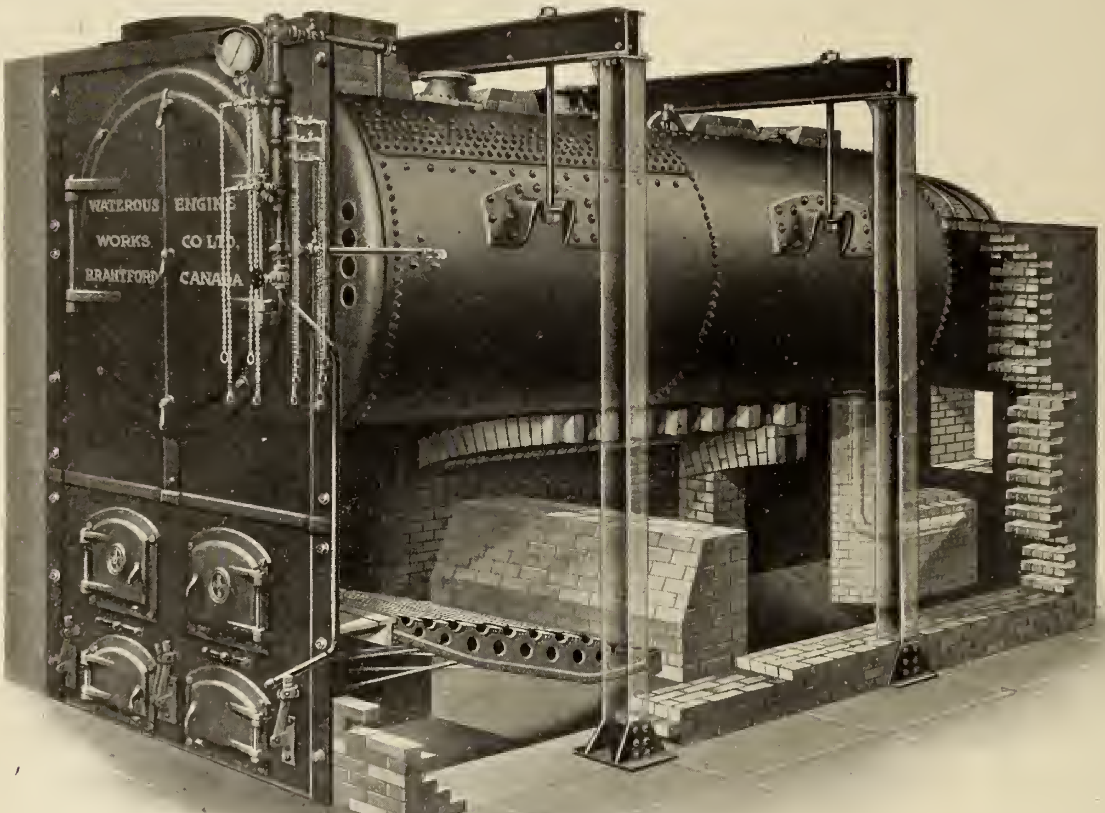
Our PINHOLE GRATE burns—ANYTHING. Special Bars for Brickyards.

Files Stokers

Hand Operated

With the Installation of Files Stokers Six Boilers Now Do the Work of Eight Boilers

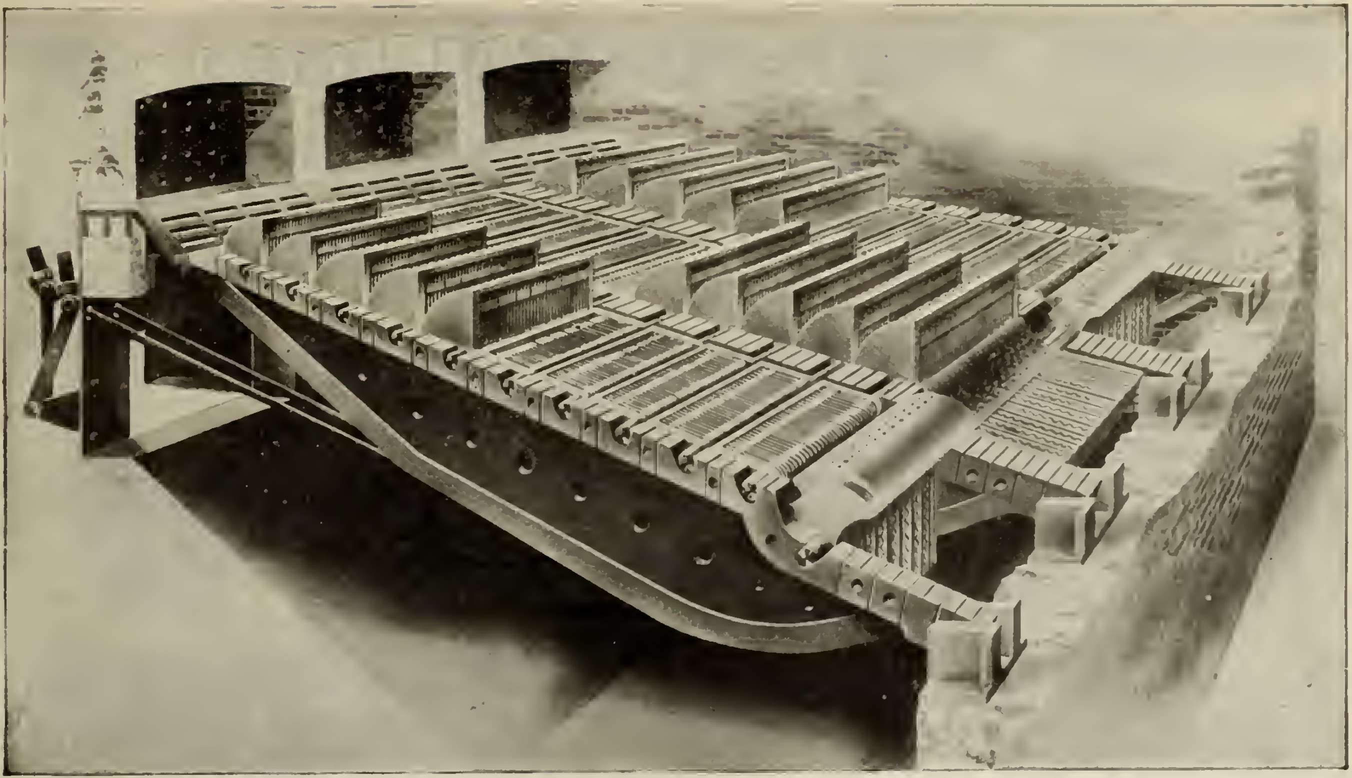
WE have on our files a letter from a manufacturing company reporting the discontinuance of two out of eight boilers after the installation of Files Stokers. Increased efficiency is the answer! Besides the time saved in operating six boilers instead of eight think of the amount of fuel saved. A Files Stoker installation to be sure soon pays for itself.



We invite you to see Files Stokers at the C. A. S. E. Exhibition

Waterous

BRANTFORD, ONTARIO, CANADA



Users Testify to the Saving Power of Files Stokers

ONE user of Files Stokers says a single installation (3,600 H.P.) saved enough coal to pay for the stoker investment in five months.

The average rating for this period was 223%.

Another user has written to say "While we have not made an actual test we would judge the saving in coal to be 10% to 15% as our load increased 25%. We are now able to obtain required steam without difficulty, which we could not do with down-draft furnaces."

Quoting from the letter of a third user the fuel-saving merits of Files Stokers is attested as follows: "Our Files Hand Stokers have now been installed about two years, during which time they have paid for themselves twice over if we consider the saving in fuel."

Files Stokers Achieve Results because:

1. They give correct distribution and proper proportion of air according to load carried.
2. The fuel bed is at all times kept clean and uniform.

You will be interested in the details of design of the Files Stoker. Write for complete information.

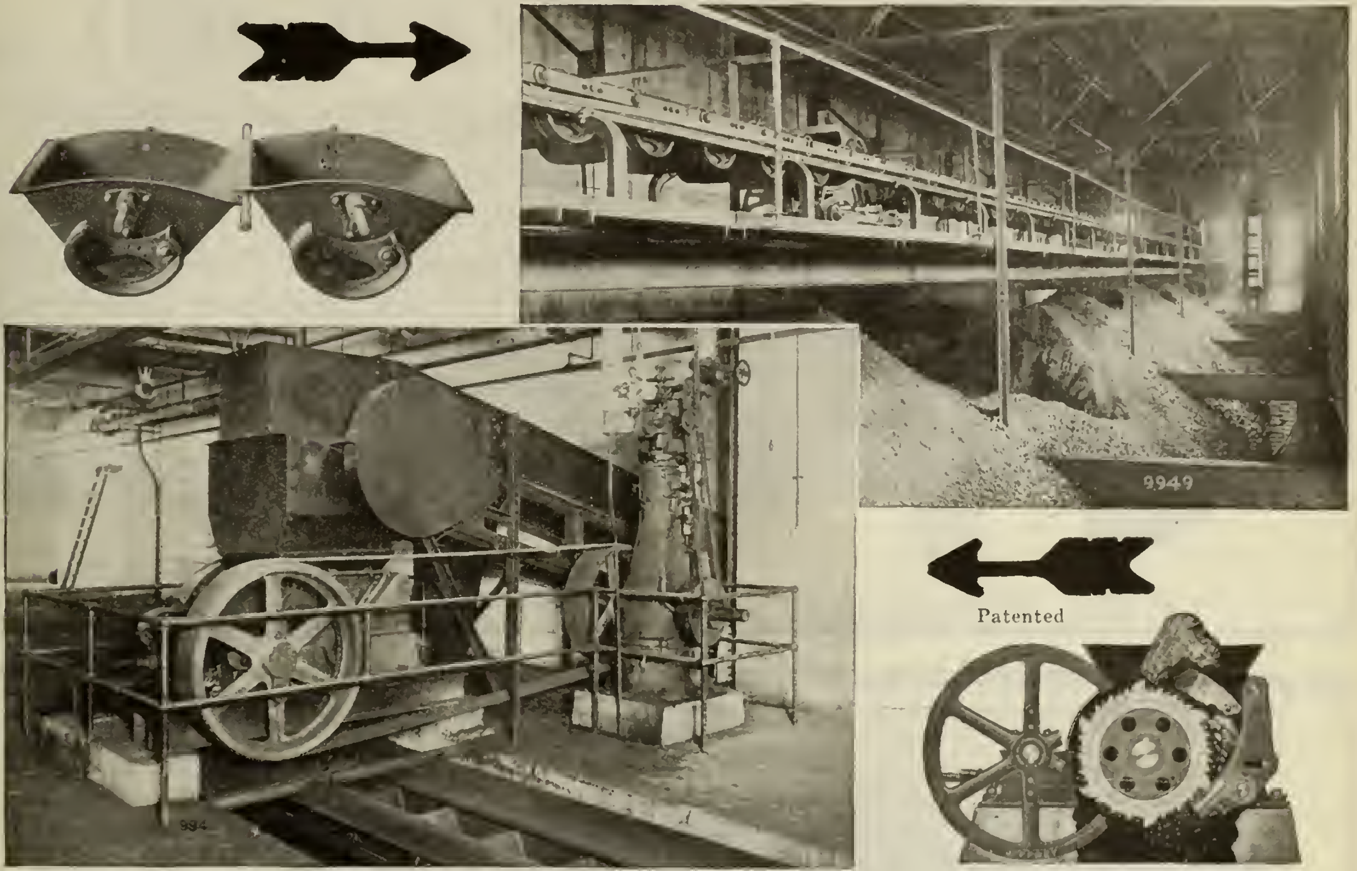
A Combination That Insures
—Low Cost Handling of Both Coal and Ashes
—A Constant Supply of Properly Sized Coal

Upper Run of Jeffrey Carrier



In basement showing lower run of Jeffrey Carrier beneath Jeffrey Single Roll Crusher.

The Jeffrey Pivoted Bucket Carrier has a working principle which ordinarily combines in the one carrier the work of at least one elevator and two conveyors, in that it handles both coal and ashes. Its economical installation is usually for a capacity of 50 to 175 tons coal per hour.

The Jeffrey Single Roll Crusher enables the power plant to crush its own coal, at a moderate cost for stoker use, where lump or unsized coal only is available, and where stoker sizes cannot be secured from the mines.

A wide range of capacity requirements is met by Jeffrey complete coal and ashes handling equipment, including: Track and Weigh Hoppers; Crushers; Bucket Elevators; Conveyors of the Bucket, Belt, Steel Apron, Pan, Scraper, Drag Chain, Spiral and other types; Skip Hoists; Portable Bucket Loaders and Belt Conveyors; Industrial Locomotives, etc.

Let Jeffrey Engineers diagnose your coal and ashes handling requirements.

Detroit Underfeed Stokers are equally well adapted to small boilers

You can profitably install Detroit Single Retort Side Cleaning Stokers under very small boilers. Those shown above are installed in connection with three 165 horse power Horizontal Return Tubular Boilers.

Under even the smallest boilers Detroit Underfeed Stokers will show a saving of from 15 to 20 per cent over the ordinary method of hand firing. The installation can conveniently and economically be applied to existing boilers in both large and small plants. Practically no excavation is required.

Many typical installations of Detroit Underfeed Stokers have been made in both public and private buildings, including such well known plants as the

Dixie Terminal Building, Cincinnati, Ohio
National Home for Disabled Volunteer Soldiers, Johnson City, Tenn.
New Detroit Municipal Garage Building, Detroit, Michigan
South High School, Youngstown, Ohio
Buffalo Hospital of the Sisters of Charity, Buffalo, N. Y.

Saving 3 Tons Of Coal Daily with FISHER Steam Traps

A manufacturer may believe he has a device the world needs. The real test comes in actual service—strenuous, pitiless service—that soon puts apparatus out of the running unless it is built to withstand such conditions.

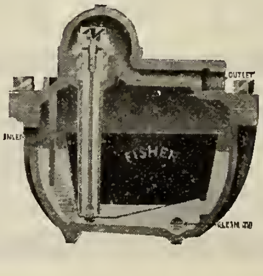
There is a multitude of steam traps on the market, but we do not believe any one of them will stand up in difficult service like the Fisher.

Read what this Fisher user says. The letter tells its own story:

> "We installed quite a number of these traps at your suggestion and replaced a number of traps of other makes and we find on checking up that after the changes have been made we have made a *saving* in our coal consumption of approximately *three tons in every twenty-four hours.*
>
> "We are, therefore, more than pleased with the performance of these traps and will take pleasure recommending them to our friends.
>
> J. GREENEBAUM TANNING CO.,
> (*Signed*) per H. E. Horne, Supt.,
> North Milwaukee, Wis."

A trap that earns a letter like that deserves investigation. Will you let us send you complete information? Simply ask for the "Fisher Trap Book."

The Fisher Governor Company
Fisher Avenue, Marshalltown, Iowa, U.S.A.



JENKINS
Bronze
Swing Check Valve

Equipped with Disc Holder and Composition Disc

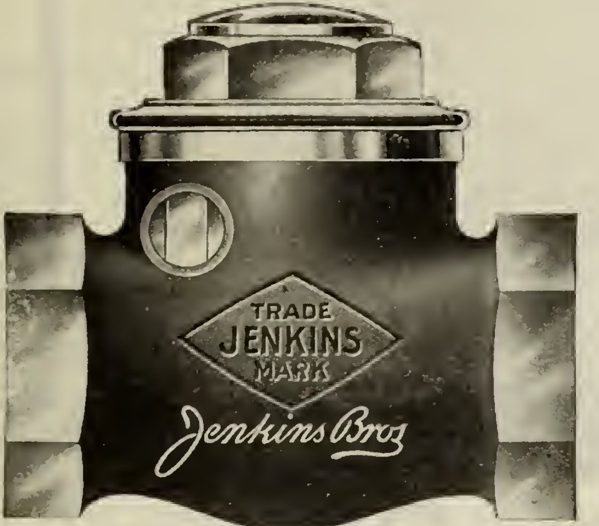


FIG. 475

Perfectly adapted for use in either horizontal or vertical position.

A strong, durable valve that will function satisfactorily. Angle of seat assures valve opening readily at low pressures while the shock of closing in the most severe service is absorbed in the line piping.

These Bronze Swing Check Valves have the Jenkins Renewable Disc feature. Disc lifts well out of passage. Hanger is heavy and has large bearing surface for carrying disc holder. Hanger pin is long and provides ample wearing surface.

Fig. 475, shown above, is the standard pattern made for 150 pounds working pressure. Flanged end valves, Fig. 476, can be supplied if desired.

This and the other Diamond-marked valves in the complete Jenkins line are fully described in Catalog No. 9—free on request.

Jenkins Valves

SINCE 1864

—a type for every plant

THE most important of all power plant problems is the correct burning of coal. In the larger central station, coal constitutes 40 per cent. of the total cost of operation. In the average boiler room itself 80 per cent. of the total expense is found in this one item.

There is a "Jones" Stoker for every requirement, regardless of the size of the plant or the boiler, the nature of the fuel or the range of the load—whether the plant is old or new. "Jones" Stokers are also extensively used in various industries for chemical, metallurgical and enameling furnaces, in fact, wherever efficiency, control of heat, and smokeless operation are desired.

All "Jones" Stokers are characterized by unmatched simplicity, sturdy construction, and therefore by lower maintenance costs. They consist of one or more simple self-contained retorts with no moving parts in the fire.

All embody the highest development of the underfeed principle of combustion — originated and perfected in the "Jones" Stoker. More economy in fuel burning is thus assured with ability to burn all Canadian coals smokelessly.

Every type of "Jones" Stoker is provided with automatic control of fuel and air, which insures efficiency at all rates of operation. Where stokers are applied to boilers an even steam pressure is automatically maintained. Where applied to industrial furnaces, both the quality and quantity of the heat is controlled.

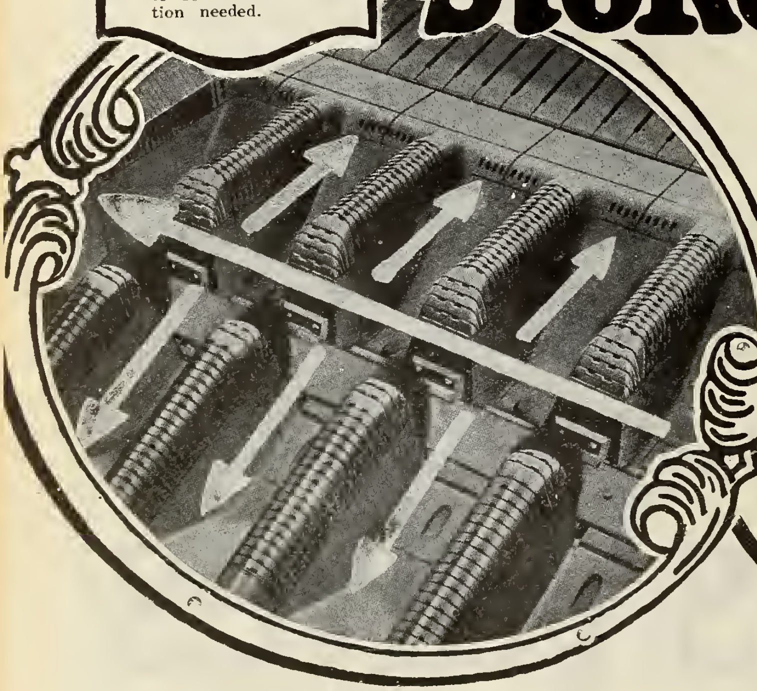
How can you know which type you need? Ask for bulletins covering any types you are interested in.

The Under-Feed Stoker Co. of Canada, Ltd., 146 King St. W., Toronto
Sales Agents for "Jones" Stokers, "Riley" Stokers and "Murphy" Automatic Furnaces

Jones Stokers

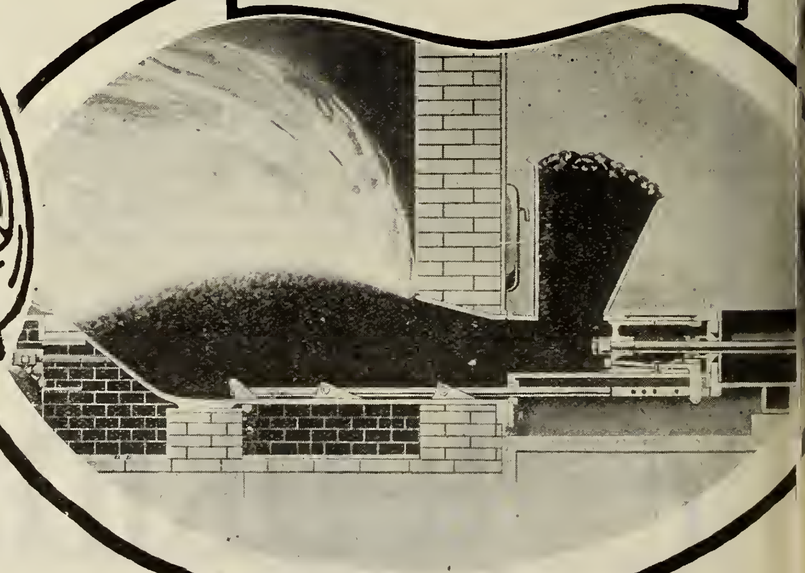
"Lateral Retort"

"Multiple retort" in everything but price. Makes available for every plant the high capacity of the multiple retort at low cost. Coal follows path of arrows. Only 6 to 18 inch excavation needed.



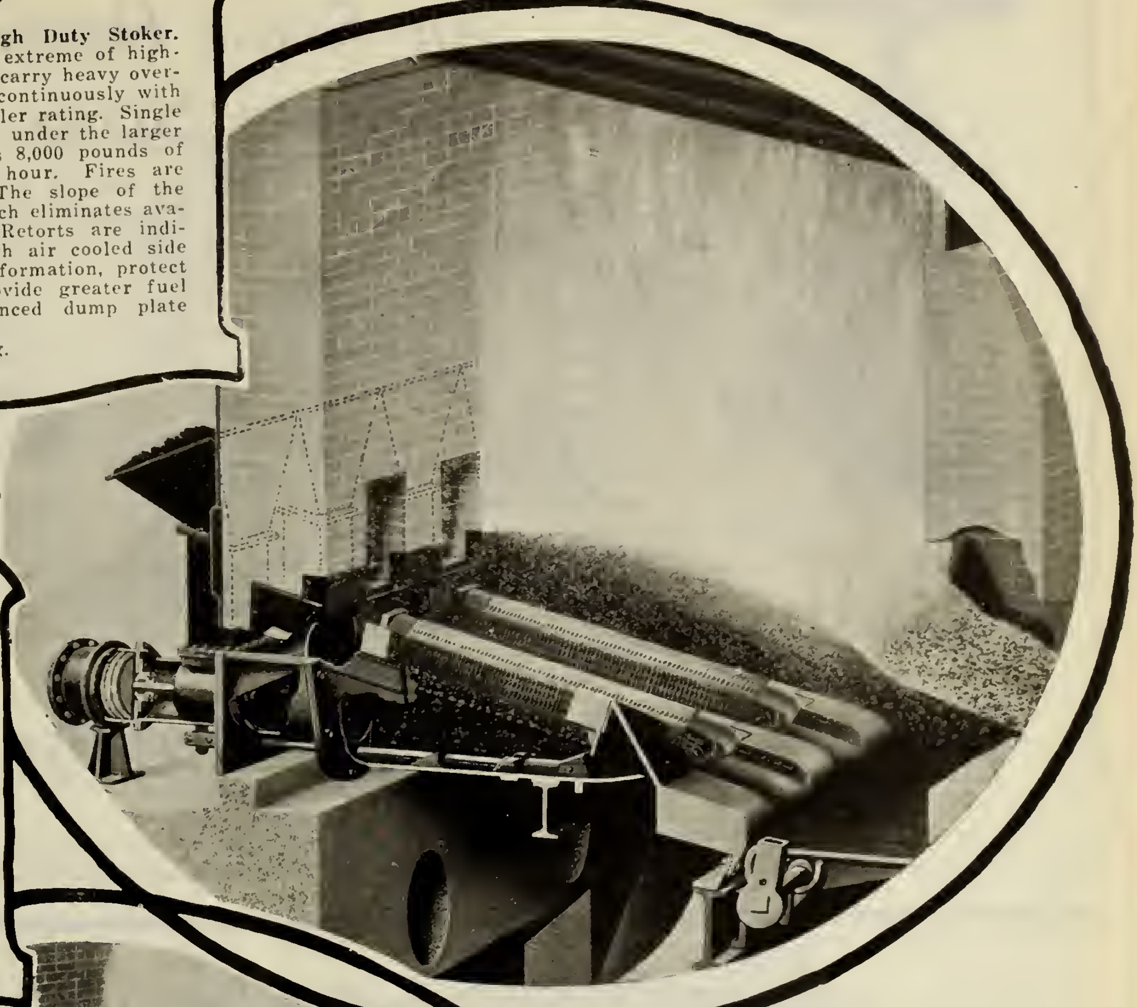
"Standard"

—a stoker that embodies the basic "Jones" features. Moderate in first cost. No special excavation required for ash pit. Simplest under-feed stoker. There are more "Jones' Standard" Stokers under Return Tubular Boilers than all other makes of stokers combined. The "Standard" Stoker is widely used for industrial heating furnaces. This stoker has a fuel burning capacity of 1,000 to 12,000 pounds of coal per hour. Single units serve boilers up to 200 H.P.



"A-C"

Automatic-Cleaning High Duty Stoker. A stoker for meeting the extreme of high-duty service—designed to carry heavy overloads of 200% and over continuously with peak loads of 300% of boiler rating. Single "A-C" Stoker installations under the larger boilers burn as much as 8,000 pounds of coal to each boiler per hour. Fires are cleaned automatically. The slope of the fuel bed is only 11°, which eliminates avalanching of live coal. Retorts are individually controlled. High air cooled side tuyeres prevent clinker formation, protect side walls and also provide greater fuel bed area; simple, balanced dump plate easily operated.
Write for "A-C" Catalog.



"Side-Dump"

Self-Cleaning Stoker meets the needs of a wide range of plants for a self-cleaning stoker that may be installed at moderate cost.

The side dump plates drop the ash into shallow ash pits, slightly below the floor line, permitting easy removal. Only slight excavation required. This stoker has a fuel burning capacity of from 1,500 to 1,800 pounds of coal per hour and serves boilers up to 300 H.P. in size. The basic "Jones" features make this stoker a fuel, labor and money saver. Ask for description.

An Extra Heavy
Forged Steel Stop Valve

This Edward Valve was developed for the most severe service—high pressure oil still lines, and is especially suited to extremely high temperatures and pressures. (Up to 500 lbs. and 1,100 deg. F. intermittent temperature).

The body and bonnet are of forged steel. The body offers least resistance to flow and the minimum sectional area is equal to the pipe area. The bonnet is of the union type with outside stem and yoke. The union ring is also forged steel and the packing nut of monel metal.

The Edward Protected Seat and Disc, a distinctive feature of Edward Valves, may be reground or renewed.

These valves can be packed under pressure. Stem, seat and disc are of monel metal.

This forged steel valve is also made with the plug type seat and disc (Catalog Nos. Globe 682, Angle 683).

A Service to the Nation

Man's mastery over nature is strikingly exemplified in our great modern system of marketing which feeds the greater part of the nation in constant defiance of time, distance and season.

The cold storage industry has made tremendous strides in refrigerating and insulating efficiency, by improved methods of controlling moisture, humidity and temperature and better means of ventilation and circulation.

The importance of properly insulated, perfectly fitting cold storage doors and windows is now generally recognized:

Architects, engineers, owners and superintendents have learned that "The Plant is only as Good as its Door."

There are many exclusive features in Jamison Doors,—greater structural strength, heavier hardware reinforcements, double seals of contact, ease of operation, longer life and fewer repairs,—as insured by "The Seal of Satisfaction."

Architects and Engineers

Aside from a complete stock of standard size doors ready for immediate shipment, Jamison built-in refrigerator fronts to specifications meet all sorts of special requirements.

A request addressed to "Desk 11" will bring our detailed, illustrated catalog, describing our entire sample line.

JAMISON Cold Storage Door Co.

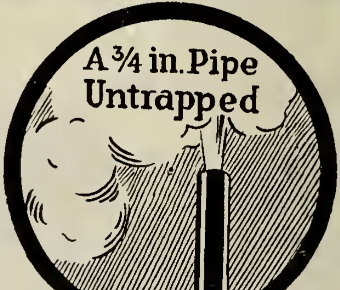
1c a Day Saves $5.74 Daily

AN UNTRAPPED ¾-in. steam pipe in your plant would waste 820 lbs. of coal every 24 hours. At the present cost of coal that means a loss of $5.74 a day—$1,722 a year.



Perhaps there are several untrapped or poorly trapped lines in YOUR plant at this moment! If so, you can prevent enormous waste by installing the Steam Trap Sarco. The ¾-in. size costs only $9.45 list.

At that price the Sarco will cost about 1c a day even if you charge off 33 1-3% of its costs per year. And after three years it will go right on saving money for years, at no cost to you—for thousands of Sarcos have been in continuous service for more than ten years.

Isn't the Sarco a worth-while investment on that basis, especially when you may try it 30 days without charge and demonstrate that it will do as claimed?

You can purchase three Sarcos for the price of one bucket type trap, and the Sarco will do the same work.

In addition, the Sarco screws right into your pipe line and eliminates the cost of building a platform or digging a pit.

Write to-day for Booklet J-33 and follow the road to steam conservation

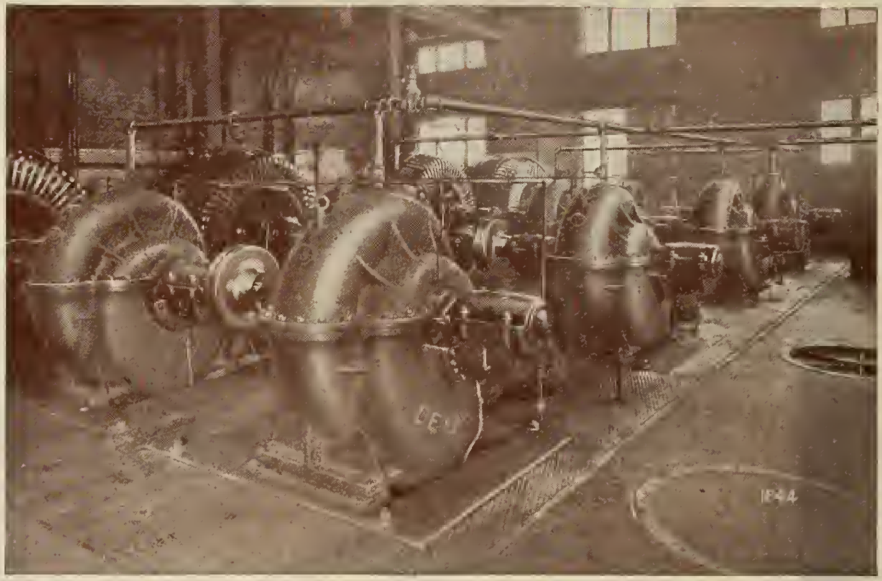
87.2% PUMP EFFICIENCY SHOWN BY DE LAVAL PUMPS AT TORONTO



SOME years ago the City of Toronto, Ontario, installed four motor-driven centrifugal pumps of European manufacture at the John Street main water works pumping station. It was subsequently decided to replace these pumps, and after receiving competitive bids, four De Laval pumps, guaranteed to develop 81% efficiency when delivering 20,000,000 Imperial gallons per day against 108 lbs. pressure, were purchased. One of these pumps when tested by Prof. Robert W. Angus established a new record for centrifugal pumps, showing AN EFFICIENCY OF 87.2% when delivering 22,240,000 Imperial gallons per day against a total head of 267.6%.

It behooves the prospective purchaser of a centrifugal pump to consider this matter of efficiency carefully, since in many instances he could not afford to use an inefficient pump even if it were given to him free of charge. You can easily figure this out for your own conditions, knowing the price you have to pay for electrical current per KW. hour, the amount of water to be handled, and the head pumped against.

Our engineers will be glad to consult with you on pumping problems. Ask for Leaflet B-100.

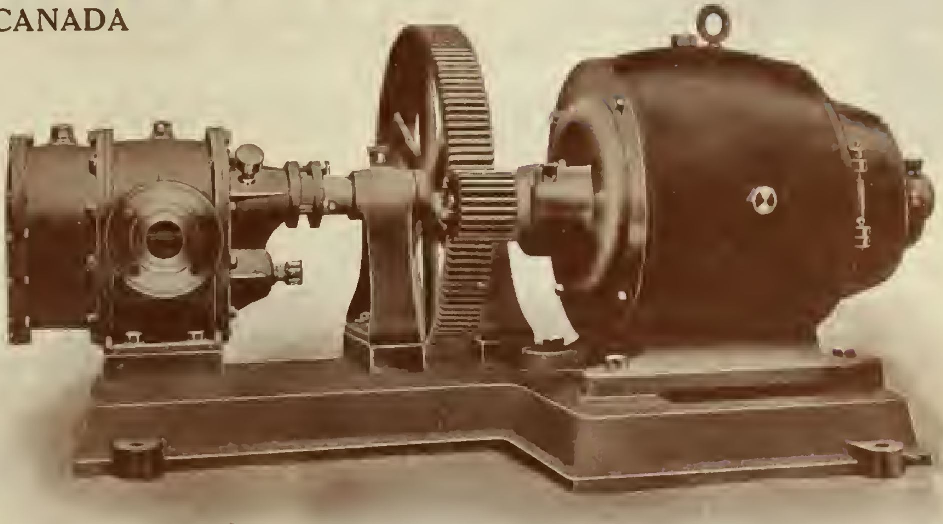
The "ALBANY" Water Sealed ROTARY PUMP

MADE IN CANADA

No Other Pump Like it

Patented in
All Countries



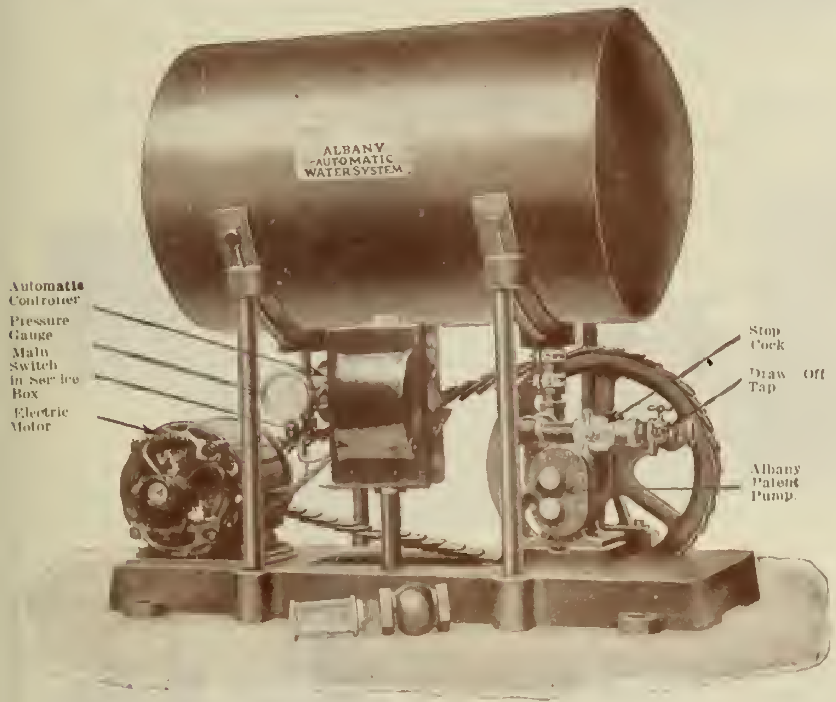
$175 with 60 Cycle Motor

$185 with 25 Cycle Motor

The "Albany" Patent Water-Sealed Rotary Pump is suitable for dealing with gas exhausters, oil, wine, vinegar, brine, acids, spirits, domestic water supplies, etc.; it is ideal for fuel-oil burning systems. No valves in these pumps—nothing to get out of order. Made in sizes from 100 to 60,000 gallons per hour. Either Belt or Motor driven.

Albany Automatic Water System

Practically Silent in operation



THE "ALBANY" AUTOMATIC WATER SYSTEM is without doubt the most compact system on the market. It occupies a floor space of only 2 ft. 9 in. x 1 ft. 6 in. Shipped complete as shown in the illustration.

ADVANTAGES: Low operating cost—small installation cost—no cumbersome and expensive storage tank—absolutely automatic and will furnish fresh water from the well. Suction lift up to 22 feet.

OPEN THE FAUCET AND THE PUMP STARTS. Close the faucet and the pump stops. The automatic switch starts and stops the pump as and when required.

The whole apparatus is built and lined up on a substantial cast iron base. Every part is direct connected. The pump is self-priming and is washerless.

CAPACITY 300 GALLONS PER HOUR.

ALBANY PUMPS ARE NO EXPERIMENT. They have been in use in Canada since 1908. Many satisfied customers testify as to their durability and lack of repair expenses.

Have us explain the pump more fully

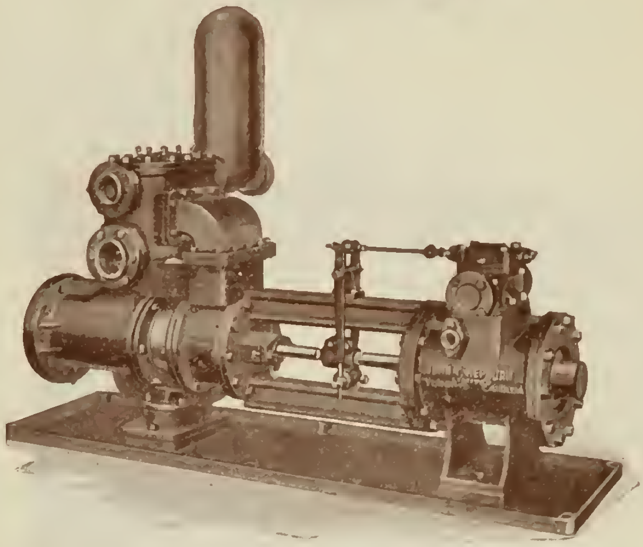
Hepburn Pumps

Installed
in the
New Morgan
Building
Montreal

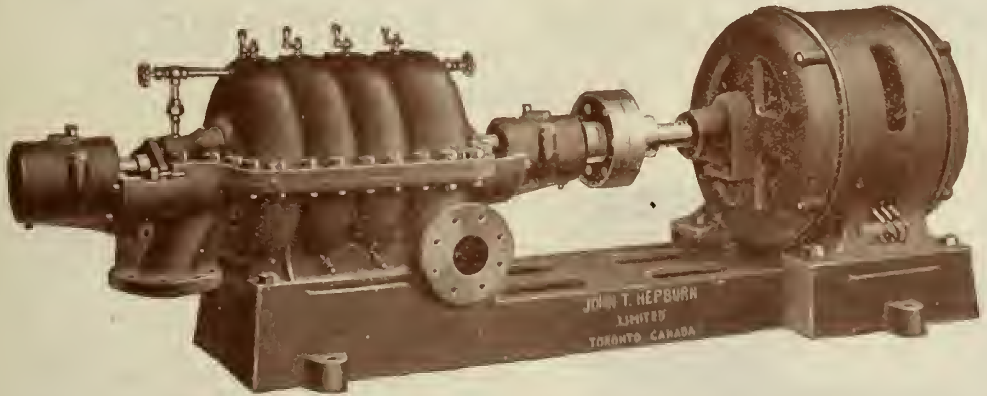


Four Hepburn pumps are used in the Morgan extension, two for boiler feeding and two as vitalizers in the heating system.

The two Boiler Feed Pumps, 12½" x 9" x 12", return the condensation to the boilers in a system of 70,000 sq. ft. of direct radiation. They are of the horizontal ram type, as illustrated above, with mechanically operated valve.

Two Hepburn Standard Vacuum Pumps, 11" x 14" x 20" are also employed in maintaining a vacuum in the heating system of the new building.

Hepburn Pumps for Waterworks Service



As a storage safeguard in connection with the water system, the district of North Vancouver has installed a 3-inch 4-stage Hepburn Pump in Lynn Canyon, to operate against a head of 600 feet.

Dependable performance is the reason behind these and many other installations of Hepburn Pumps.

Let us furnish you with complete information in regard to these pumps.

"John Crane" Special Ammonia Packing

The channels act as wipers, preventing the ammonia film from escaping to the outer air. The babbitt face is non-abrasive and keeps rods in excellent condition. Change to John Crane Style 104 Special. It will well repay you.

Style 100—Babbitt foil, impregnated with purest graphite. Compressible. Flexible.

+

Style 400--Resilient duck channel. Metallic face

=

Style 104 Special Alternate rings of styles 100 and 400, providing metallic low friction wearing face. Channels wipe rods free of ammonia film. In sets as shown or cut from spirals as you need it.

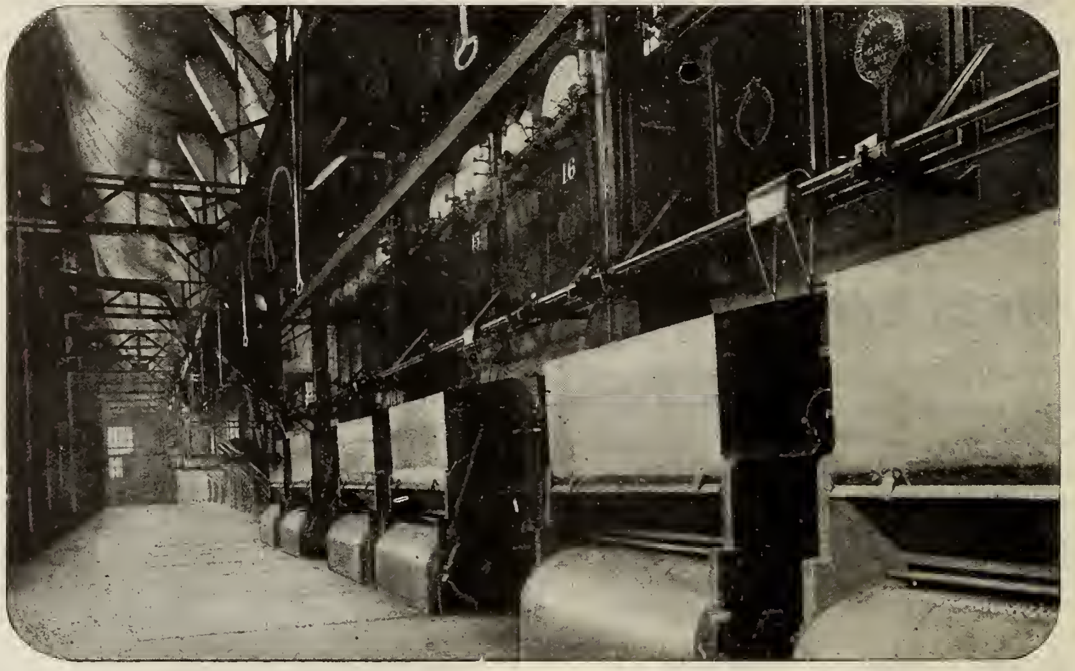
Dependable Power Plant Equipment



G. & McC. Sectional Water Tube Boilers

Every Part Subjected to Steam Pressure is Made of Forged Steel

This important feature of the design and construction of G. & McC. Sectional Water Tube Boilers give them a great advantage over all types of ordinary boilers. Other features of these boilers include large steam and water drums and connecting nipples of increased size, thus providing greater combustion area and increased steaming capacity.

Complete Information Promptly Supplied.

Power Plant Efficiency Dependent on Engineer

By MELVERN F. THOMAS*

Although Good Boilers, Auxiliary Equipment, Draught and Fuel Are Essential to Secure Economical Results, in the Last Analysis the Man in Charge is the Decisive Factor

THE actual service and efficiency of a steam plant is dependent upon the engineer in charge and the men under his direction.

This statement is probably true in most branches of industry, but the purpose of this article is to discuss the relation of the engineer and his assistants to the service rendered by their plant.

If the design and construction of the plant is correct for the service required, it is the duty of the engineer to maintain the apparatus in good condition, operating only the parts necessary to supply the demand.

If the construction of the plant is not suitable to the service required, it is the duty of the engineer and his assistants to put forth their best efforts in operating the equipment to the best advantage without allowing their zeal to condone unsafe conditions that would endanger the lives of themselves and others.

Depends on Engineer

The owner of the average steam plant is dependent upon the engineer for recommendations as to the equipment required from time to time for improving the efficiency of the plant and replacing obsolete or worn out apparatus. To know what is required, and what can be installed as the best paying investment, an engineer must be constantly studying the requirements of his particular plant. He must know what other engineers in similar plants are doing and how and why they are doing it. He should keep up with the "times" by reading technical newspapers and by contributing articles on the operation of steam plants and steam plant equipment.

The engineer is more valuable to his employer if, when a certain piece of equipment is required for efficiency he can advise as to its suitability for his plant, not merely state that the new device seems to be O. K. in another part of the world where conditions may be entirely different, and where coal may cost only half what he pays for it.

Produce and Use

There are two branches of service in the modern steam plant,—one being to produce steam and the other to use it. To secure the highest efficiency, naturally, the problem is to produce the greatest amount of steam at the smallest cost for fuel, labor and overhead and to use the least possible amount of steam to supply the demands of the service.

On the eve of the C. A. S. E. convention in Toronto, Melvern F. Thomas is pre-eminently fitted to decide the dependency of efficiency in the power plant on the operating engineer. Himself one of the foremost consulting engineers in the Dominion, his experience and power of analysis has put within his grasp the solution of hundreds of the biggest power plant problems in Canada, such as the C. P. R. building, Toronto; the Massey-Harris plant at Brantford; the Queen's University plant at Kingston; and the Parliament Buildings at Ottawa. As past president of the Ontario section A. S. H. and V. E., his comment on the value and importance of the engineer in effecting combustion efficiency is worthy of the most serious attention of all Canadian executives.

To secure high efficiency in the production of steam requires good boilers, furnaces, draught and auxiliary equipment, suitable fuel, and operating men who will work together as a team.

To save coal it is vital to watch "the 7 keeps."

KEEP boilers clean outside and inside so that they will absorb the heat generated in the furnaces.

KEEP brick settings and baffle walls tight to keep out cold air and to prevent the hot gases from short circuiting and wasting heat up the chimney.

Watch Air Holes

KEEP the furnaces and grates or stokers in good repair and watch for air holes in coal bed and the waste of coal through the ash pit.

KEEP dampers adjusted to give the amount of draught required by the load. Too much draught means too much air passing through boilers and too much heat carried up the chimney. Draught reduced too low will impair the capacity of the boilers and cause furnace walls and arches to burn out.

KEEP high load on boilers by "cutting out" units when not required. Overloads on clean boilers, properly set, will not reduce efficiency or injure equipment, while underloading usually results in low efficiency.

KEEP sufficient help to properly operate and maintain the plant.

To Cut Overhead

KEEP down overhead expenses by not installing superfluous apparatus, but avoid the other extreme of insufficient capacity which results in heavy costs of cleaning and repairs made during holidays and nights.

It is the engineer's duty to operate the steam generating plant as a department of the manufacturing plant and supply the raw material, "steam," at the lowest possible cost, thus doing his part to conserve Canada's limited supply of imported coal.

The distribution and use of steam may also be under the supervision of the engineer, or if this is not practical in a particular case, he should be in close touch with those who control the use of steam and should be prepared to give to the "office" a statement of the quantity supplied to each department of the plant.

---

*Consulting Engineer, Toronto, Ont.

Do not let any department consider the steam supply as "free air" which can be "turned on" and forgotten.

The steam generated in the boilers is generally used in one or more of the general services of power, industrial service and heating.

While the steam used for power is of first importance in large stations; it is not considered within the scope of this limited discussion.

Losses Continuous

The industrial steam includes all services throughout the factory, where it is used in the process work either as high or low pressure. This service is usually "on" whenever the factory is running and the losses are continuous.

The piping to distribute steam for industrial purposes is often altered and temporary branches installed to supply new or re-located apparatus. This piping may never have met the covering man, and it will surprise industrial executives to know how much heat can be wasted by bare pipes.

For example, how much heat is wasted (and coal required to produce it) in one year of 300 days of 10 hrs. from 100 feet of 2-in. uncovered pipe, under steam at 50 lbs. gauge pressure, located in a building where the temperature averages 68 deg.?

The surface of this pipe is 60 sq. ft., and the difference in temperature between the pipe and the air is 230 deg. The heat loss will be a little more than 1 boiler horsepower, which during the year will waste 6 tons of coal.

From 4 to 5 tons of this coal could be saved by proper covering.

The engineer should watch all alterations to steam piping in the system and make sure that any unused pipes are cut off and that those under steam are covered. Bare pipes in the industrial steam distribution system not only waste coal but the condensation interferes with the flow of the steam, reduces the capacity of the piping and frequently causes leaks at joints.

Steam Traps Vital

The water from steam condensed in the piping and in steam-using equipment must be removed, and steam traps installed to prevent steam from escaping with the water. The engineer should have all steam traps inspected frequently and defective ones repaired at once.

There is no apparatus in use in a steam plant that is so often found defective as the steam trap, which leads the writer to conclude that many engineers do not fully appreciate the heat loss and trouble with return piping due to defective steam traps.

Condensate from the piping and process work should be returned to the boilers, wherever it is practical to do so, since it still contains from 10 to 15% of the heat of the steam from which it was condensed and is free from boiler scaling ingredients.

Our climate requires buildings to be heated 6 to 7 months of the year, low-pressure steam with direct radiation being largely used for this purpose.

With such systems the greatest difficulties are:

Removal of air from the piping and radiation.

Removal of water from the piping and radiation.

Control of the steam to give the amount of heat required without waste.

Reclaiming the hot water from condensed steam.

Obtain Best Results

The air and water must be removed from the system before steam can fill the radiators and give the full value of the heating surface. Either air or water collecting in the mains or branch pipes will interfere with the circulation of the steam and reduce the capacity of the boilers by necessitating an increase in pressure.

In a properly constructed heating system only a few ounces of steam pressure above that of the atmosphere is required to secure complete circulation through all the radiators.

If the engineer can heat all parts of the building evenly in a short time after "turning on" the steam he can then cut off the steam or greatly reduce the pressure on mild days.

Factory heating plants are designed to heat the buildings in the coldest weather; in the vicinity of Toronto there should be capacity to warm the building to 68 degs., with the outside temperature 15 degs., below zero, but the average through the winter months requires less than half this capacity.

The following tabulations give the average temperatures and percentages of the maximum load for the six winter months.

	Average Temperature	Degrees Rise to 68°	Per cent. of maximum load (15° to 68°)
Nov.	37°	31°	37
Dec.	28	40	48
Jan.	22	46	55
Feb.	21	47	57
March	29	39	47
April	42	26	31

The average heating load may be obtained from the last column, and during the season, it is only 46 per cent. of the maximum heat required to warm the building to 68° when the outside temperature is 15° below zero.

Big Steam Saving

If the engineer can arrange to cut off the steam from the radiation not required, there will be a saving of 40 per cent. to 50 per cent. of the steam that would be condensed if all the radiation is kept in service throughout the season.

An example, to reduce this possible saving in coal consumption, may give the importance of regulation a more definite meaning.

Suppose 1000 sq. ft. of radiation is filled with low pressure steam for six winter months. It would condense about 1,100,000 lbs. of steam which in an ordinary plant will require 60 to 70 tons of coal. The possible saving by properly controlling the steam supply is nearly half of this fuel.

If excess radiation is not cut off in mild weather, windows will be kept open more than necessary for ventilation, and the engineer will find his plant consuming coal to heat the outside atmosphere.

The engineer should insist that all condensed steam be returned to his plant to give hot water for feeding the boilers. Boiler feed water at 170° instead of cold water at 45° from the city mains will give over 10 per cent. saving in coal.

Traps Source of Loss

A common loss in steam plants is steam escaping through traps, especially those on high pressure piping, and by looking at the trap it will often be found that the steam passing through the trap overheats the water in the return system, escaping through vents from the receiving tank, or interferes with the condensation draining from the piping causing trouble with the pumps which is concealed by cold water being introduced.

This condition often results in a constant flow of hot water running to the sewer.

Do not allow any hot water to escape if you wish to save coal!

While the engineer and his assistants should consider themselves responsible for the service and efficiency of the steam plant, they must have constant co-operation from the owners or others in charge of the plant if satisfactory service is to be obtained.

The horsepower constant is the number of horsepower per pound of mean effective pressure developed by an engine when running at its normal speed. It will be different for different speeds. Knowing the constant, one need only multiply the mean effective pressure (obtained from an indicator diagram) by this constant to know what indicated horsepower the engine is developing. Evidently by the definition, the horsepower constant is all of the "PLAN" formula except the P.

A brass polishing paste, said to give satisfactory results, is composed of camphor gum, 1 oz.; alcohol, 2 oz.; spirits of ammonia, 2 oz.; spirits of turpentine, 4 oz.; candle paraffin, 1 lb; clean tallow, 1 lb.; tripoli, 1 lb.. For compounding, first dissolve the camphor in the alcohol, then melt down the tallow and paraffin and stir in the liquids and the tripoli. Before cooling, the paste may be packed in boxes of sizes convenient for use.

Utility of the Modern Pump in the Power Plant

By ARTHUR MURPHY

A General Description of the Characteristics of the Better Known Types, With a Few Pointers on Their Maintenance and the Modern Tendency Toward Auxiliaries

IN DISCUSSING the relative value of the many different types of pumps found in the modern power house in Canada, it is interesting to note that one of the first pumps on record was made in 1675. In that year Sir Samuel Moreland was decorated by King Charles the Second for demonstrating a "certain powerful machine to raise water."

Twenty-four years later Savery exhibited before the Royal Society of England a model engine, which consisted of two copper receivers alternately connected by a three-way hand operated valve. When the water had been driven out by the steam, cold water was poured over its outer surface creating a vacuum through condensation and causing it to fill again while the water in the other reservoir was being forced out. The modern pulsometer used for pumping dirty and abrasive liquids, where steam consumption is ignored, is in principle similar to Savery's engine.

Thomas Newcomen in 1690 invented an engine in which the steam was admitted from the boiler to a cylinder, raising a piston by its expansion, assisted by a counterweight on the other end of the beam actuated by the piston. The steam valve was then shut and the steam condensed by a jet of cold water, creating a vacuum in the cylinder, atmospheric pressure forcing the piston downward.

This type of pumping engine with automatic control of the valves, was in common use by 1725, and changed in form but little for seventy years, until James Watt separated the steam cylinder from the condenser.

From Watt's time until 1850, the steam driven pump made but slow progress, low pressures and slow speeds being used. As late as 1859 the city of Hamilton installed two vertical beam compound condensing engines directly connected to plunger pumps, using steam at 30 pounds pressure and exhausting to a 24 inch vacuum.

The flywheel alone on each engine weighed 24 tons, the complete unit standing over 51 feet high, with a capacity of 1800 gallons per minute.

A modern centrifugal unit with a capacity of 20 million gallons a day, occupies a floor space of 20 feet by 8 feet, with less than 7 feet in height.

Centrifugal More Recent

The first application of centrifugal pumps was made by Denis Papin in 1703. Over fifty years later Euler took up the problem.

In 1818 a volute pump known as the "Massachusetts" was brought out, with double suction openings and an open impeller. This was improved by R. Carthy in 1830.

In 1901 a single stage pump was constructed with backward curved vanes, discharging through a series of diverging guide passages into whirpool chamber of ordinary form. Efficiencies of 48 per cent. were obtained.

The different types of pumps which find favor to-day may be divided roughly into two main divisions: Reciprocating, including direct acting steam, crank and flywheel; plunger and pistons types; and the rotating type, including Roots type, gear pumps and centrifugal pumps.

The reciprocating pump consists of piston or plunger fitted to a cylinder and provided with suction and discharge valves. This is the oldest form of pump and to-day finds use around the power plant for pumping water, boiler feed work and in many cases for pumping oils, both lubricating and for servo-motors or operating cylinders on turbines.

Slip Reduces Efficiency

This type of pump has a constant displacement, that is the quantity of water discharged is practically the same as the plunger displacement, the slight loss of capacity being due to defective packing, leaking pistons and stuffing boxes, or delayed closing of the suction and discharge valves.

Fig. 2—Vertical Pump.

This loss, called "slip," is stated as loss in percentage of the displacement, or expressed as (1-Ev) where Ev= volumetric efficiency.

In new pumps the slip is small, rarely exceeding 2 per cent. in plunger and ring types, in slow speed outside packed plunger pumps with no leakage past the plunger it may be even less.

Excessive slip of 5 per cent. or over is an indication of leaking piston or defective valves. The hydraulic efficiency is high, the only losses being due to friction in the valves and water passages, the mechanical efficiency may be low, due to frictional losses if the packing is excessively tight.

Packing Kept Tight

A cross section of a direct acting steam pump is shown in Fig. 1. This is an outside centre packed plunger type used widely for boiler feed purposes. The valve arrangement and the air chamber necessary on all pumps with plungers are shown. The advantage of this pump lies in the fact that leakage can be kept to a minimum since any loss is to the outside.

The single acting pump is not as steady in speed as the duplex. The direct acting steam pump is simple, low in cost, requires little attention in service, and is remarkably flexible, a great range of capacities, and heads being ob-

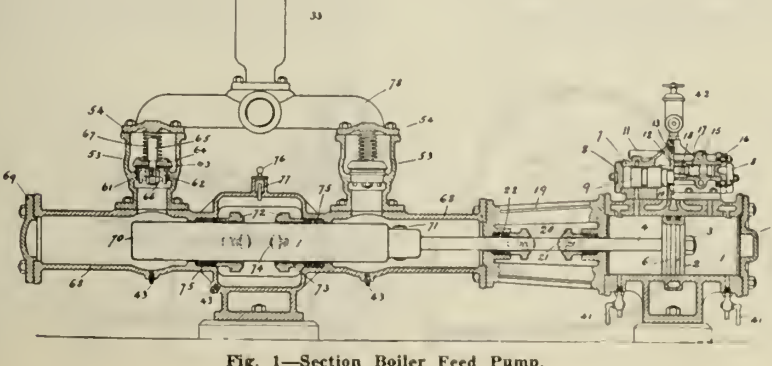

Fig. 1—Section Boiler Feed Pump.

tainable simply by controlling the steam with a throttle. It is built in capacities from 1,000 pounds to 350,000 pounds per hour, with speeds ranging from 30 to 70 strokes per minute.

The direct acting duplex steam pump gives a steady flow and requires small air chambers. The valve on one side is actuated by the motion of the piston rod on the other side, resulting in equal speeds for both sides and smooth, continuous operation. This type is sometimes made in compound and triple expansion.

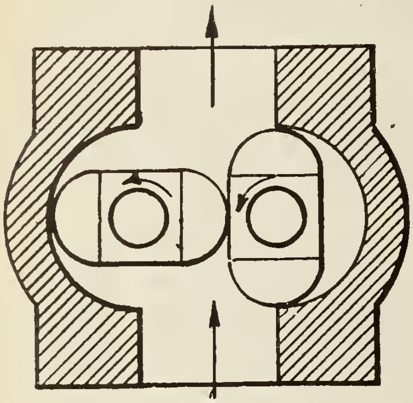

Fig. 3—Roots Pump.

The direct acting pump is used for high pressures, 3,000 to 10,000 lbs. per sq. in., because of the ease of control, a rod from the accumulator to a valve serving equally as well as complicated control mechanism, in regulating the speed.

In places where floor space is at a premium the vertical direct acting steam pump illustrated in Fig. 2 finds favor as well as being useful for deep well and mine use.

In mines it is customary to place the suction and the discharge pipe in the vertical line, the pump being raised and lowered by means of a cable as the level of the water changes.

Find Use as Vacuum Pump

The direct acting steam pump is also widely used for vacuum service, the difference between it and the general service pump being in the diameter of the cylinder and the modifications of the valves. For vacuum pumps the water cylinders are much larger than the steam end, the valves having much lighter spring tensions.

For boiler-feed pumps the plungers are about 1-3 the size of the steam cylinders; below 150 lbs. pressure pistons are used, above 150 lbs., outside packed plunger pumps find favor.

The direct acting steam pump has some disadvantages, including slow speed and the difficulty of regulating the length of the stroke. Speed is usually controlled by manual operation of a valve on the steam line; every pump, however, should have a speed regulating device which will prevent racing when the vacuum in the suction line is destroyed or when the inlet valve sticks open.

Steam consumption may be high in the simple direct acting pump, sometimes up to 200 lbs. per h. p. hour. Cut-off being at the end of the stroke advantage cannot be taken of the expansive force of the steam.

Exhaust Heats Feed Water

This, however, for boiler feed work may not be any disadvantage, if all the exhaust steam be used for feed water heating.

A few hints on operation of direct-acting pumps may be of service to the engineer; not that he is ignorant of them, but it seems to be a chronic habit in some plants to pay all the attention to the large units and think of the auxiliaries only when they fail to work —much the same attitude taken by the general public toward public utilities such as electricity and water—to be thought about only when some accident temporarily deprives them of the luxury.

The writer has been in plants where the boiler feed pumps would not operate till the steam pressure was over fifty pounds; on loosening the packing they worked quite satisfactorily on much less pressure.

Pumps Require Care

Make sure that there are no leaks in the suction side of the pump; if any air leaks, the pump will not operate properly, sometimes not at all.

The economical operation of a pump depends to a great extent on the kind and condition of the packing in the stuffing boxes and pistons, its quality, adaptability to the particular requirements, and method of placing in the stuffing boxes and plungers.

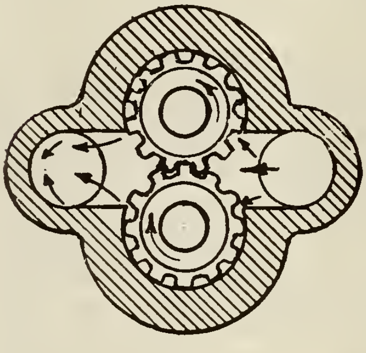

Fig. 4—Gear Pump.

A number of narrow rings are better for packing than a few wide ones. The rod should be kept tight with the least possible pressure on the packing.

When cutting packing rings, the length should be such that the ends do not come together within ⅛ inch. When put in the stuffing box, rings are put in with the joint broken, preventing leakage through the spaces.

Tighten packing only sufficiently to stop leaks; a slight leakage at the water end is not harmful.

A little cylinder oil and graphite applied to the rod will keep it smooth and bright, a condition favorable to durability of the rod and packing.

Pumps should be kept clean internally and externally.

The water end stuffing box of a pump may be lubricated by putting a heavy grease on the piston rods, or a good cylinder oil may be used. Some of the grease works into the stuffing boxes and furnishes better lubrication than can be secured by water alone. Care must be taken not to use too much oil as it must not go beyond the stuffing boxes and contaminate the water.

When one side of a duplex pump makes a quick stroke it indicates either that the stuffing box gland of the opposite side is too tight, or that the packing in the cylinder of the side making the quick stroke is wearing out or has perhaps given away. A broken discharge or suction valve will also cause a jerky motion of the pistons.

The regular inspection of the screen in the separating chamber in the suction pipe renders frequent inspection of the interior of the pump unnecessary.

When a pump has to run faster one week than another in order to supply approximately an equal supply of water, the plunger and valve should be examined because such a condition indicates leakage.

When a pump fails to lift water after standing some time it should be primed by filling the barrel with water and starting it slowly. If it stills refuses to raise water the suction pipe, valves and plungers should be examined. If the packing is dry and hard, air will leak into the pump and it will not work properly. The packing should be well soaked first and if it does not soften, be replaced with new.

Pumps that are exposed to low temperatures in winter should be provided with removable drain cocks or plugs, for emptying cylinders and valve chambers of water, also allowing the water to flow out of the suction pipe.

Stoppage of the suction pipe or chambers is generally indicated by a jerky action or pounding of the plungers or water pistons; on the other hand, a

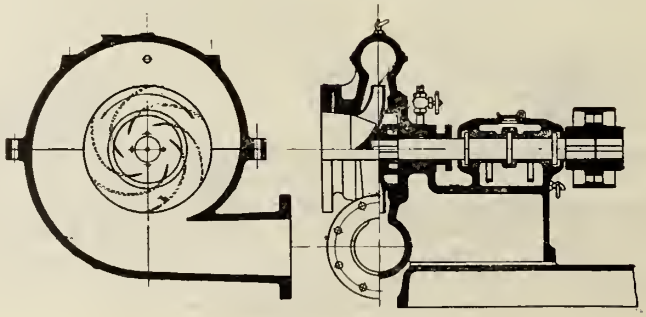

Fig. 5—Single Stage Pump.

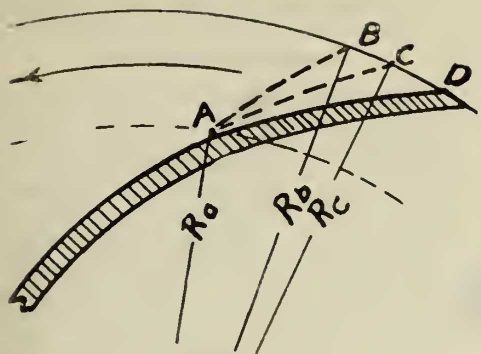

Fig. 6—Impeller Tip.

dull thud at the end of the stroke is often due to lack of air in the air chamber, or when the speed is high, its lack of capacity in the air chamber.

The steam end should be lubricated with good cylinder oil and given the same care as any engine.

Pumping Hot Water

It is difficult to lift hot water any great height by suction because of the fact that water boils at lower temperatures with decrease in pressure, releasing vapors which destroy the partial vacuum produced by a pump. For this reason any pumps handling hot water such as boiler feed pumps, should be arranged if possible so as to have the water delivered to them under pressure, or if not, to have a very short lift.

Crank and Flywheel Economical

The crank and flywheel pump may be considered to be a direct acting type with the addition of a balance wheel, driven by steam, electricity, internal combustion engine or in some cases by hydraulic turbines.

The advantages of this type over the direct acting, when using steam as motive power are many, such as steady running, uniform discharge and decreased steam consumption due to early cut off. The stroke being constant, the discharge may be approximated by counting the number of strokes and allowing a small loss due to "slip."

The large triple expansion high-duty plunger pump is used largely in water works especially in districts where electric power is not available and steam is used. It is capable of high duties, is reliable and will last for years. The valves used in this type are of rubber between three and five inches in diameter, the four and a half inch size being common, placed in valve decks in order to get a sufficient number in a small space, a large pump having several hundred valves.

A triple expansion pump in the John Street Pumping Station in Toronto, showed an overall efficiency of 96 per cent. indicated water horse-power over indicated steam horsepower.

The rotating type of pump is made with two rotating elements called pistons, impellers or lobes. The impeller is made with one or more teeth designed for continuous contact at a uniform velocity. In the Roots rotary pump shown in Fig. 3, there are but two teeth with two rotating elements rolling together as shown by the arrows. Water is trapped between the lobes and the pump case and is forced to the discharge side; the contact of the impeller at the centre preventing water returning to the suction side. The discharge is continuous but not uniform, hence air chambers are necessary. These pumps are built for heads from 10 to 200 feet, with claims for efficiency from 75 to 85 per cent.

Another type of positive displacement rotating pump is made with one rotating element eccentrically located in the casing with 3 or 4 packing blades, which are free to slide radially in the rotor. The discharge is uniform but the speed is limited and the slip may be considerable.

Used for Fire Pumps

The gear wheel type is shown in Fig. 4, the arrows indicating the flow of liquid and the direction of rotation of the gears. This type may be run at high speeds with volumetric efficiencies, if not badly worn, of from 90 to 95 per cent., the overall efficiency varying from 50 per cent. for small pumps to 70 per cent. for large, capacities going from ⅛ to 60 gallons per minute.

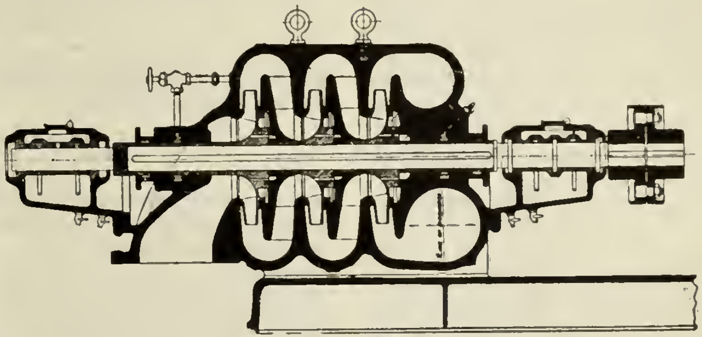

Fig. 8—Three Stage Pump.

The modern gasoline fire truck is often equipped with a gear pump. They also find a place around power plants for pumping oils.

Centrifugal Pumps

Low pressure up to 50 feet.

Medium pressure.

High pressure.

Vertical shaft. Horizontal shaft.

According to the number of inlets per impeller:

(a) Single entry; (b) Double entry.

According to the type of impeller.

(a) Radial discharge; (b) Backward discharge; (c) Forward discharge.

Number of stages:

Single stage—one impeller.

Multi-stage—two or more impellers.

The centrifugal pump consists of an impeller or impellers mounted on a shaft and surrounded by a spiral casing or discharge vanes and spiral casing. The rotating impellers due to centrifugal force increase the velocity of the water passing through; the discharge vanes, if present, and the spiral casing change the kinetic energy of the water leaving the impeller, into static head.

When the discharge vanes are present it is customary to call it a turbine pump; when only a spiral casing, a centrifugal.

The present tendency is toward the elimination of the discharge vanes, decreasing the cost of manufacture and giving a pump which retains high efficiency over a greater range of capacity. The highest efficiency ever obtained in this class of pump was made without the discharge vanes.

Impeller Important

Upon the design of the impeller probably rests the success or failure more than on any other part of the pump. Impellers are of two general types—open and closed.

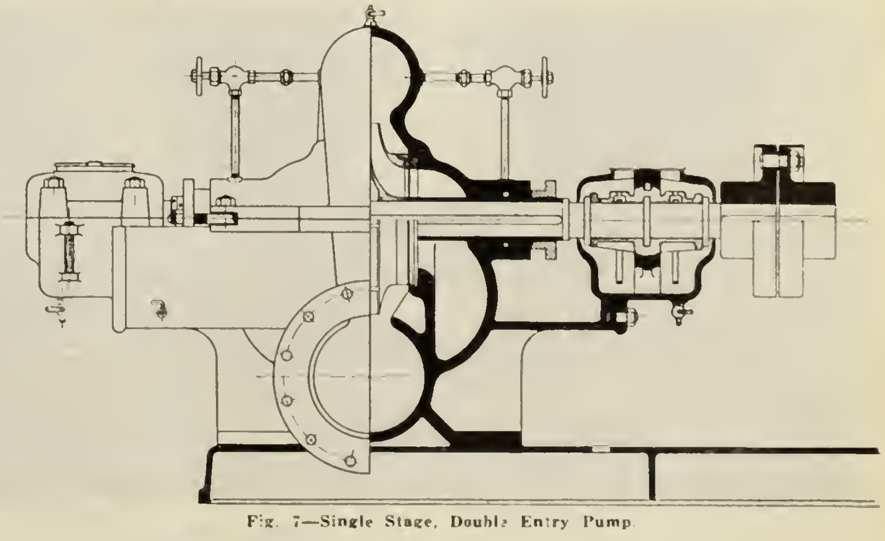

Fig. 7—Single Stage, Double Entry Pump

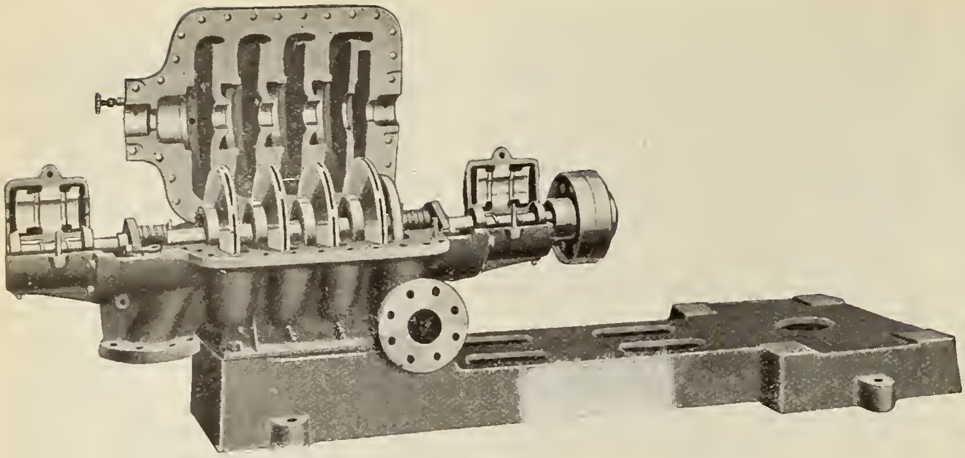

Fig. 9—Four Stage High Head Pump.

In the closed type the blades and sides are in one, in the open only the blades of the impeller are present, the casing serving as sides to guide the water.

On account of the increased leakage in the open type the trouble in keeping the impeller in its correct position and the higher frictional losses, this type has been replaced by the closed type.

The periphery of the impeller must run at such a speed that the water at exit has sufficient velocity, which on being turned to pressure in the spiral casing, will give the desired head.

Impellers should be smooth in the water passages to cut down frictional losses. In pumps for high heads and small volumes, the water passages become so narrow that it is difficult to cast them. Built up impellers are then used.

The exit and entrance angles of the impeller blade must be carefully designed, more especially the entrance. The shape of the blades between entrance and exit being of less importance as long as it is a smooth curve. The ends of the blades should be sharpened, cutting down eddy losses.

A single stage, single entry pump is illustrated in Fig. 5, the suction pipe entering at the side. With the single entry impeller there is always a heavy thrust toward the direction of the entering water. In this illustration the thrust is toward the left, requiring a substantial collar on the shaft or a thrust bearing. Thrust bearings should be water cooled or overheating will result.

On account of this feature single entry pumps are now made only in the smaller sizes, or when initial cost does not warrant much outlay such as in rough construction work, and temporary installations. The double entry impeller is free from this heavy thrust, but in order to centre it, and to take care of any slight unbalanced thrust, in the larger types it is customary to use a marine type thrust bearing. Ball thrust bearings have been used in some pumps with good results.

Cavitation and Erosion

Bad design and improper speeds result in speedy destruction of the impeller, due to cavitation. Impellers have in some pumps lasted but a few weeks, having the appearance of a sponge in places. This trouble is more pronounced in small capacity pumps in which too high a lead is attempted in one stage. Erosion is due chiefly to impurities in the water.

In the centrifugal pump there is danger of the power increasing to a point that would seriously overload the motor or the turbine should the head for any reason fall off and the discharge increase. To prevent such a condition, impellers are made with a non-overloading feature which prevents the power rising above a certain point regardless of the discharge, in some cases the power drops off with increase of capacity.

Overloading Prevented

This non-overloading feature is secured by flattening the angle of the blade tips. Referring to Fig. 6 suppose at A a small particle of water is moving along the blade to the periphery of the impeller and that it then follows the path AC. If the velocity of the water from A to C is such that the point D on the periphery of the impeller has travelled from D to C in the same time, the tip of the blade from A to D then has exerted no pushing action on the water, thus no more power is taken.

The net effect is the same as if the diameter of the impeller had been reduced from Rc to Ra. Suppose that a particle of water is travelling along the path AB and that in the same time the point D on the impeller has reached C. The power taken would then be less than in the first case mentioned, for with such an impeller the power required drops off with increase in capacity.

For these reasons a centrifugal pump should always be started with the discharge valve closed and opened slowly to the point giving the required discharge, otherwise serious overloading of the motor will occur the instant the pump has reached its normal speed.

Short Circuits Loss Stopped

There is always a tendency for water to leak from the discharge to the inlet of the impeller on account of the difference in pressures, this loss commonly being referred to as short circuiting. To lessen this loss labyrinth is used, preventing a tortuous path to the water which, with the small clearances between the rotating elements, allows little water to escape the suction side. There is also the danger of air leaking into the pump along the shaft, destroying the suction.

A packing gland is fitted on each side and a water seal is used. In Fig. 7 these glands are shown as well as the pipe from the case to the gland to make

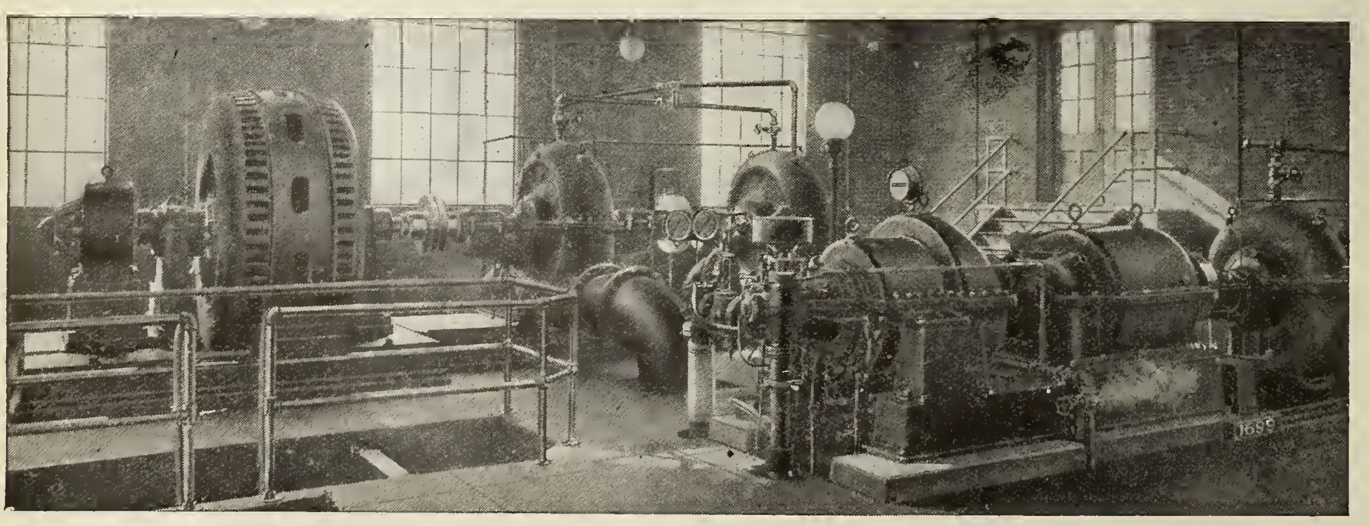

Fig. 10—Modern Waterworks Pumps.

the water seal, the labyrinth packing on both sides of the impeller is also shown.

Use Several Stages

When the head is high in comparison to the capacity, experience has shown that it is better to divide the head into two or more stages. If in a pump of small capacity an attempt be made to secure a high head with one impeller the hydraulic passages become so narrow that excessive frictional losses result, accompanied by low efficiencies, corrosion and pitting of the passages.

A cross section of a three stage medium head pump is shown in Fig. 8. The water passages are of fair size.

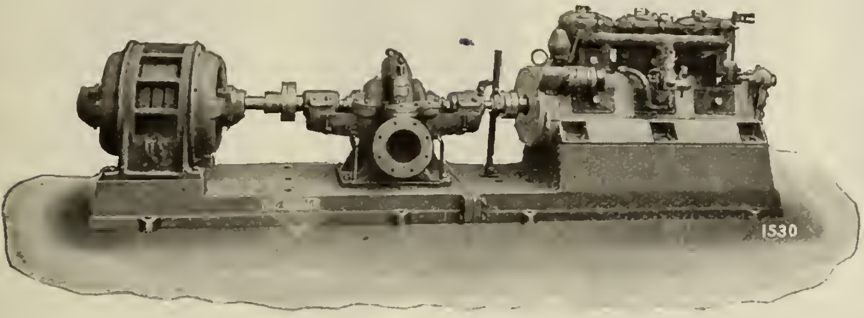

Fig. 11—Pump With Reserve Engine.

Turning to Fig. 9 we have a four stage high head pump of small capacity; 150 gallons per minute against 650 feet head. The impellers are of large diameter with narrow passages. Impellers are always single entry in multi-stage pumps.

Balance Thrust

There is considerable axial thrust to be taken care of in the multi-stage pump. In some cases this is accomplished by allowing part of the discharge pressure to act against some portion of the back of one of the impellers, using a water cushion for balancing, in other types, holes in the impeller web equalize the pressure in the space inside the labyrinth seal, clearances on the outside of the impellers are made large equalizing the pressure in the outer spaces; any small thrust remaining is taken care of by a heavy marine thrust bearing on the suction side.

Adapted to Motor Drive

The centrifugal pump owes its advance largely to the ease with which it may be adapted to drive by electric motor or the steam turbine as well as its small size for a given capacity. Motor and pump speeds are such that they may be directly connected and both run at efficient speeds. A flexible coupling is always used to connect the pump and motor shafts.

Induction motors are in wide use for this service, the synchronous motor with its high efficiency and good power factor may also be used to advantage because of the small starting torque required with centrifugal pump.

Use Reduction Gears

The speed of the steam turbine is much too high for direct connection, necessitating the use of reduction gears, the loss it is claimed being from 2 to 5 per cent. The turbine is well adapted for high superheat and high vacuum which is readily secured in water works stations making the overall efficiency of the unit high.

Fig. 10 shows two single stage pumps direct connected to a synchronous motor, in the same room may be seen a steam turbine driven pump. Fig. 11 illustrates a single stage pump with direct connected motor drive on one end and direct connected gasoline engine on the other, serving as a standby in case of failure of electrical power. Such installations find wide use in small cities and towns which have access to cheap electrical power but are not large enough to warrant building a steam plant as a standby.

Priming Necessary

Centrifugal pumps if small are fitted with foot-lift valves, to prime it is only necessary to fill it with water through an opening above the pump, or through a valve on top of the spiral casing.

Larger pumps have no foot valve, so must be primed by creating a partial vacuum in the pump. In power plants where steam is available, two methods may be used, the pump may be filled with steam which on condensing forms a partial vacuum sufficient to draw the water to the impeller or an injector may be fitted to the top of the casing, the discharge valve in each case being tightly closed. If steam is available a vacuum pump operated by hand is often used.

Fig. 10 shows two large motor driven pumps and a turbine driven unit, the steam connection to the top of each casing may be seen.

It is customary in water works plants in which steam is used as motive power to speak of the performance of the unit as duty or the number of foot pounds of work done per 1,000 pounds of steam. The efficiency is also rated in percentage.

The overall efficiency of a centrifugal pump ranges from 40 to 50 per cent., the lower figure being for small pumps running at an incorrect speed, the higher for large, carefully designed pumps in water works. The highest efficiency ever recorded for a centrifugal pump was obtained a short time ago in the John Street Pumping Station, the official test showing an efficiency of 87.2 per cent.

The duty of steam turbine driven units has reached 160,000,000 foot pounds per 1,000 pounds of dry steam.

The tendency in larger power plants when large quantities of water are being used for condensers is towards the use of centrifugals, turbine or electric motor driven. Condenser circulating pumps are low head of large capacity.

Centrifugal turbine driven boiler feed pumps are finding favor for large boilers, the exhaust steam being used to heat the feet water, the advantage being in the small size and the control of capacity. The feed water can be measured accurately with a Venturi meter when the flow is steady as with the centrifugal boiler feed pumps.

Vacuum pumps used in the larger power plants are a special adaptation of the centrifugal.

In water works stations the guides vanes have been eliminated, double entry is universal, and where high heads, two or more single stage double entry pumps are run in series, 100 preference to one multi-stage pumps.

Trade Catalogs

The Conveyors Corporation of America have just issued a handsome booklet, "Representative Installations." The booklet contains illustrations of a number of notable buildings and power plants which are equipped with the American Steam Jet Ash Conveyor.

Copies of the new booklet will be sent to any engineer who is interested.

The level fuel bed Detroit Retort Underfeed Stoker which has attracted wide attention in the power plant field, is illustrated and described in detail in the new bulletin "Built on Advanced Engineering Principles" just published by the manufacturer.

Among other subjects the bulletin covers the practical application of well developed principles in the science of combustion in the design and construction of a high duty machine to meet modern requirements for heavy overloads and severe service with large boilers.

Copies may be had by writing the Detroit Underfeed Stoker Co., 320 General Motors Bldg., Detroit, Mich.

The Jointless Fire Brick Co. are offering to engineers and power plant operators their 52 page booklet, "Modern Furnace Building."

This booklet tells the complete story of the building of monolithic furnace linings. It shows how boiler furnaces, circular furnaces, pit type brass furnaces and other furnaces may be lined with this jointless lining. There are many illustrations showing how forms for special shapes, like front door arches, are made. The chapter on the making of baffles of plastic linings is very interesting.

A post card to the Jointless Fire Brick Co., Chicago, Ill., will bring a copy of booklet to anyone interested.

C.A.S.E. Convention Opens in Toronto June 25

Advantages of Common Meeting Ground Given Engineers and Exhibitors to Promote the Maximum of Efficiency in the Operation of Power Plants in the Dominion

AT THE annual convention of the Canadian Association of Stationary Engineers, which will be preceded by the banquet of the Exhibitors' Association in the main dining room of the Hotel Carls-Rite, Toronto, Ont., at 7 p.m., Monday, June 25, unusual opportunity will be given operating engineers and exhibitors to consider mutually the part the work of each plays in attaining the maximum of efficiency in the operation of power plants in the Dominion.

It cannot be denied that a common meeting ground for engineers and manufacturers, with a frank discussion of the practical results obtained from the work of each, must prove of great value to the industrial executive, who in the last analysis, foots the fuel bills.

There is so much to be done in Canada in cheapening the generation of power; in solving the ever present fuel problem and in increasing production, if the Dominion is to win her rightful place in the competitive markets of the world, that the engineer—the most important piece of apparatus in a power plant—cannot afford to neglect the slightest improvement in methods of combustion.

The engineer who would honestly serve his employer must know an economical remedy for every power plant disease.

Faces Broad Field

The field is so broad, extending from the advisability of softening boiler feed water and selecting packing that will not harden, through such widely divergent fields as the installation of stokers and the psychology of keeping firemen contented, to the analysis of flue gases, that the man who feels he can learn nothing further is simply courting disaster.

An engineer who does not keep up with the latest practice—efficient and better ways of doing things—by attending association meetings and by studying the columns of the two publications on the American continent devoted solely to the power problems of industry—*Power House* in Canada and *Power* in the United States that he may advise his employers what to buy to obtain the most economical results,is not treating fairly the executive who is paying him.

Reference to the C.A.S.E. program at the convention proper, which begins at the Central Technical School, Harbord Street, Toronto, at 9 a.m. Tuesday morning, June 26, with the official opening of the Grand Lodge, to be followed for two days by the annual exhibition of power plant equipment, makes clear the attempt of convention officials to render available to all who attend the meeting—engineers, exhibitors, and visitors alike—the best that power plant engineering has to offer.

The speakers have been asked to avoid generalities and personalities and to follow as nearly as possible the practical treatment of their subjects.

It should be noted that the list of exhibitors includes representation from:

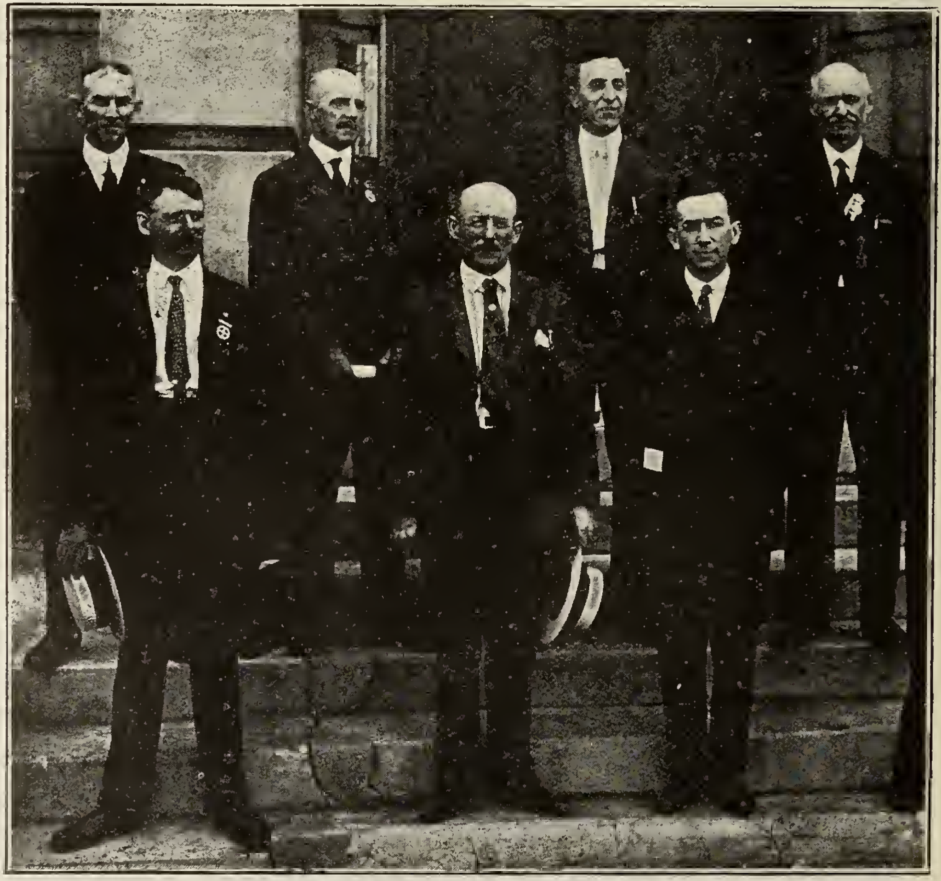
Allen General Supplies, Ltd.—fuel saving devices; The Argus Mfg. Co.—stack paints and plastic cements; Beldam Asbestos Co.—packings and grates; The Bird-Archer Co.—boiler feed water treatment; Babcock & Wilcox Ltd.—boilers; A. W. Cash Co. of Canada Ltd.—stokers; Crane Ltd.—valves; Celite Products Ltd.–heat insulation; G. E. Cole—steam traps; Darling Bros. Ltd.—pumps, heating equipment, etc.; Dearborn Chemical Co. Ltd.—boiler feed water treatment; Dart Union Co. Ltd.—unions and flanges; C. A. Dunham Co., Ltd.—radiator valves; Geo. Farrow—boiler tube cleaners; Goldie & McCulloch Co. Ltd.—boilers and engines; Imperial Oil Ltd.—lubricating oils and greases; Jenkins Bros. Ltd.—valves and packings; The Lunkenheimer Co.—valves; The James Morrison Brass Mfg. Co. Ltd.—brass goods; Magnolia Metal Co. of Canada Ltd.—bearing metals; Quaker City Rubber Co.—packing; Refinite Co. of Can. Ltd.—water treatment equipment; Shell-Bar, Boico Supply, Ltd.—feed water treatment; Stephens Chemical & Mfg. Co.–feed water treatment; Shaw Schools Ltd.—educational courses; W. R. Sexton Boiler Setting Co.—shaking and dumping grate bars; G. F. Sterne & Sons Ltd.—boiler cements; Thompson-Gordon Co. Ltd.—packings; C. B. Turner & Co.—feed water skimmers, plastic cement, etc.; W. J. Westaway Co. Ltd.—water softeners; Waterous Engine Wks. Ltd.—stokers, engines, etc.

The exhibition of power plant equipment is open to all who are interested in power plant operation.

The program for the four days follows:

Monday, June 25

7.00 p.m.—Banquet in main dining room of Hotel Carls-Rite given by the Exhibitors' Association of C.A.S.E. Following the dinner there will be an excellent program contributed by well known artists. A civic welcome will be tendered by Mayor C. Alfred Maguire of Toronto, who will formally declare the convention and exhibition open.



MEMBERS OF GRAND LODGE
Rear Row: R. E. Arnup, F. Harper, Geo. F. Galloway, and R. F. Gafton.
Front row: L. J. Ellis, Henry Wright and J. J. Sullivan.

G. C. KEITH
Secretary

EARL GORDON
2nd Vice-President

J. THOMPSON
President

HOWARD FLETCHER
1st Vice-President

GRANT E. COLE
Past President

L. M. ARCHIBALD
Treasurer

GEO. M. WILKINSON
Assistant Secretary

E. F. HETHERINGTON
Chairman Entertainment Committee

H. H. GEE
Chairman Reception Committee

C. B. TURNER
Chairman Exhibit Committee

OFFICERS OF EXHIBITORS ASSOCIATION

Jack Armour will entertain. He will be accompanied to the convention by Fred R. Low, editor of *Power*, New York, presidential nominee of the A.S.M.E.

"A big time" vaudeville act through the courtesy of Arthur Murphy, editor of *Power House*.

Brief speeches by C.A.S.E. members, including Ald. W. H. Shaw and G. J. Soucy.

Duncan R. Cowan will lead the singing with Chas. E. Musgrave at the piano.

J. Thompson, Toastmaster.

7.30 p.m.—Wives of delegates to Grand Lodge will be entertained at a theatre. Assemble at Carls-Rite before 7.30. C. B. Turner will be in charge of the party.

Tickets of Admission:

Members of C.A.S.E. in good standing will be admitted free on presentation of due card paid up to date. Tickets to others than members may be obtained from the secretary of the Exhibitors' Association or at the door of the Banquet Hall.

10.30 p.m.—Special meeting Grand Lodge Officers at Hotel Carls-Rite.

Tuesday Morning, June 26

9.00 a.m.—Official opening of Grand Lodge in Technical School Library.

Secretary Treasurer's Report.

10.00 a.m.—Official welcome to Engineers and Exhibitors by Dr. A. C. McKay; short addresses by others, R. McLaren, President Toronto No. 1 C.A.S.E. presiding.

11.00 a.m.—Official inspection of Exhibition by the Grand Lodge.

12.00 noon.—Lunch.

Tuesday Afternoon, June 26

1.00 p.m.—Grand Lodge Session. Exhibition open all afternoon.

11.00 p.m.—Tour through Technical School Mechanical Departments including Boiler, Engine, Pump Rooms, etc., conducted by M. B. Watson, director of the Department of Engineering. Mr. Watson will give an explanation of the equipment and the tour will be a real education.

Tours have been arranged for Tuesday and Wednesday to accommodate visitors and it is the wish of the director that visits to the power plant be made only at the hours specified in the program.

Tuesday Evening, June 26

8.00 p.m.—Entertainment in the Main Auditorium of the Technical School.

Radio Concert (weather permitting) conducted by M. B. Watson who will give a brief explanation of radio.

Moving picture films both comic and engineering will be shown.

Ladies are especially invited.

8.00 p.m.—Exhibition open until 10.30.

10.00 p.m.—Drawings for Prizes. Lucky numbers: Ladies—1 and 7. Engineers—1, 5 and 11.

Any prize not immediately claimed will be presented to the owner of the card next drawn.

Wednesday Morning, June 27

9.00 a.m.—Meeting Grand Lodge in the Technical School Library.

9.30 a.m.—Exhibition open until 10.30 p.m.

12.00 noon—Lunch.

Wednesday Afternoon, June 27

1.30 p.m.—Meeting Grand Lodge.

4.00 p.m.—Tour through Engineering Department conducted by M. B. Watson, director of the department. It is specially requested that visitors confine their visits to the engineering department to the hours mentioned in the program.

Wednesday Evening, June 27

8.00 p.m.—Entertainment in the Main Auditorium.

Radio concert (weather permitting).

Engineering and comic films.

GEO. F. GALLOWAY,
Vice-President and Acting Grand President.

10.00 p.m.—Prize Drawings. Lucky numbers: Ladies—2 and 6. Engineers—2, 7 and 10.
Any prize not immediately claimed will be presented to the owner of the card next drawn.

Thursday Morning, June 28

9.00 a.m.—Meeting Grand Lodge in Technical School Library.
Election of Officers.
Selecting place of next convention.
9.30 a.m.—Exhibition open until 1.00 p.m.
10.00 a.m.—Annual Meeting Exhibitors' Association.
11.00 a.m.—Open Meeting Grand Lodge for the Installation of New Officers.

Thursday Afternoon, June 28

1.30 p.m.—Tour of City—Free to delegates and their wives, leaving Technical School at 1.30 and landing at Picnic Grounds at 2.30.

GEO. J. SOUCY,
Chairman Convention Committee.

2.30 p.m.—Picnic at Exhibition Park given by Toronto No. 1 C.A.S.E.
Supper will be served in the Horticultural Building, where the presentation of prizes will be made.

PICNIC

Thursday Afternoon, June 28

At Exhibition Park, Toronto,
Under the auspices of Toronto Lodge
No. 1, C.A.S.E.

1. One Hundred Yards Dash—Engineers and Exhibitors.
   1st Prize......................
   2nd Prize......................
2. Balloon Race—Engineers' wives only.
   1st Prize......................
   2nd Prize......................
3. One Foot Hop Race—Engineers and Exhibitors.
   1st Prize......................
   2nd Prize......................
4. Ladies Candle Race.
   1st Prize......................
   2nd Prize......................
5. Backward Running Race—Engineers only.
   1st Prize......................
   2nd Prize......................
6. Ladies' Clothes Pin Race.
   1st Prize......................
   2nd Prize......................
7. Men's Smoking Race, 75 Yards and Return—Engineers only.
   1st Prize......................
   2nd Prize......................
8. Potato Race—Engineers' Wives or Daughters only.
   1st Prize......................
   2nd Prize......................
9. Wheelbarrow Race, 50 Yards and Return. Each team to consist of Engineer and Exhibitor. 1st Prize only.
10. Little Boys' Race—Sons of Engineers.
    1st Prize......................
    2nd Prize......................
11. Little Girls' Race—Daughters of Engineers.
    1st Prize......................
    2nd Prize......................
12. Soft Ball Game—Engineers vs. Exhibitors. Box of cigars to winners.

The Stoker Manufacturers' Association held the annual meeting at the Lake Placid Club, Essex Co., New York, from May 29-31. S. A. Armstrong, president, spoke of the benefits that must accrue to the association from the facts given by papers on stokers that were presented at the Fuel Section of the A.S.M.E. last December. He also recommended the addition of a standing committee on industrial relations, which would permit of study tending to the promoting of friendly relations and mutual confidence between employer and employee.

The Under-Feed Stoker Co. of Canada, Ltd., 146 King St. W., Toronto, are installing three Riley Stokers under 500 h.p. B. & W. boilers in the plant of J. R. Booth Co., Ottawa, Ont.; four standard side-dump stokers in the new power house of the departmental store of the Morgan Realties, Ltd., Montreal, P. Q.; three stokers under 150 h.p. return tubular boilers at the Chateau Lake Louise C. P. R. Hotel, in Alberta; and two Riley stokers at the Donnacona Pulp & Paper Co.'s plant, Donnacona, P. Q.

C. H. Raessner has been appointed district sales manager for the Foxboro Co., Inc., manufacturers of recording and indicating instruments. His central office is at 1510 Monadnock Bldg., Chicago, Ill.

After making repairs on a pipe line connecting with an engine, it should be blown out, the steam being allowed to flow into the steam chest, the ports of which have been either plugged or covered by the valve.

Drains for steam pipes should be provided at all points where it is possible for water to accumulate. Some may be for use only when putting the line into points where there is even slight difference in pressure should not be joined together or to the same trap, as the difference will prevent the proper operation of the one of lower pressure. If a still lower pressure or constant discharge is maintained beyond the point of junction, as in the Holley loop, the foregoing does not apply.

UNCOVERED IN ANY OLD SPOT

In packing valve stems or piston rods, never use old packing that has been removed. It has lost its elasticity and there is danger of it scoring the rods.

* * *

Can you beat it? The fireman thought a Skye Terrier was an Irish angel.

* * *

For running condensing, the principal change required in the valve setting would be to secure earlier closing of the exhaust valves of the low-pressure cylinder so as to obtain the same cushioning effect from compression of exhaust steam of lower pressure.

* * *

Wife of Engineer (on visit to Toronto with hubby to attend C. A. S. E. convention)—Horrors! I forgot to turn off the electric iron!

Husband (thinking of banquet in the main dining room of Hotel Carls-Rite given by Exhibitor's Association)—S'all right. Nothing will burn long. I forgot to turn off the water in the bath tub.

* * *

Load factor is defined as the ratio of the average load to the maximum load during a certain period, such as a week or a month. This should be distinguished from plant factor, which is the ratio of the average load to the rated capacity of the plant.

* * *

There was a Galt flapper with flapping
goloshes
Who married a fireman who used to
fight Boches.
But the flap and the fight
Didn't mix up just right—
She's gone to see what kind of firemen
Oshawa has.

* * *

A two-phase induction motor may be reversed by changing two leads of either phase if it be a four-wire machine, or by interchanging the outside leads if it be a three-wire machine.

* * *

Some buy the lowest-priced oil because it is the cheapest they can get; others buy oil best suited to their use even if high priced, because it is the cheapest in the end.

* * *

The total friction of a given engine remains practically constant under all loads and should not exceed 5 to 8 per cent. of the full load capacity of the engine. It increases with steam pressure from 30 to 70 lb. after which only slight increase is noted. Increased speed generally increases the total friction, but not always.

* * *

The furnace temperature must be kept high enough to combust the gases but not so high as to melt the ash.

Developing Hydro Electric Plants in Ontario

By FREDERICK A. GABY, B.A.Sc., A.S.M.E.[*]

Phenomenal Growth of Market for Electrical Energy in Province Due to Fact That Commission Has Discharged Its Trust by Distributing Power to Municipalities at Cost

THE province of Ontario is richly endowed with water powers, widely distributed over an extensive area. Its boundaries comprise an area of over 400,000 square miles, and its surface waters drain both to the Atlantic and to the Arctic oceans.

It is customary to present round numbers representing total water power potentialities for various districts, and for various countries, and when such totals have been given for Ontario it has been usual to estimate the total water power of the province at about 6,000,000 horsepower, but this estimate is of relatively little significance for purposes of comparison with other provinces unless first of all a uniform basis for comparison has been established.

We are aware of the fact that the character and extent of the hydrometric and other data available for a determination of the water-power potentialities of many rivers varies greatly and subsequent investigation of particular streams not infrequently has resulted in greatly increasing early estimates of water power available from such streams, while, in other instances, the reverse has been the case.

Such an experience has been encountered in Ontario. In view of such facts, the known water-power possibilities of the province cannot satisfactorily be compared with other countries where estimates may include a greater percentage of hypothetical considerations.

Needs Much Research

There remains much research yet to be prosecuted in connection with undeveloped water storage.

Any person looking over detailed maps of the northerly portions of the province cannot fail to be greatly impressed with the great number, and in the aggregate, the extensive area of the lakes spotted over these areas.

We shall leave therefore, the question of grand totals of water powers by stating that preliminary estimates, which include Ontario's share in the water powers of her international waters, have indicated a total of some 6,000,000 horsepower, of which some 1,300,000 horsepower has already been developed.

Ontario is the owner of Canada's equity in the water power of the Niagara river and of the international portion of the St. Lawrence river, and even if the actual power that can be developed under the present limitations of Treaty regulations or of engineering considerations be considered, it will be found that the power potentialities of these streams constitute a very large proportion of the available power in the Province.

Shared With Quebec

Next in importance to the Niagara and the St. Lawrence rivers is the Ottawa river and its tributaries, the more important of which in Ontario are the Blanche, the Montreal, the Petawawa and the Madawaska rivers. The power on the main stream, which constitutes part of an interprovincial boundary, is shared by the provinces of Ontario and of Quebec.

Frederick Arthur Gaby graduated from the University of Toronto in mechanical and electrical engineering in 1902. In 1907 he was appointed assistant chief engineer of the Hydro-Electric Power Commission, being appointed chief engineer in 1912. Prior to this Mr. Gaby was with the Canadian General Electric Co., the Nova Scotia Steel & Coal Co., and the Toronto Niagara Co. He is a Fellow of the Royal Society of Arts of Great Britain, and a prominent member of the Lakeshore Golf and Country Club.

Other important water powers are found in the Trent River watershed, tributary to Lake Ontario. There are nearly thirty sites, of which about one-half have been developed with an aggregate capacity of 50,000 horsepower, leaving undeveloped sites with an aggregate capacity of some 15,000 horsepower. Tributary to Lake Huron are water power streams with an aggregate potentiality at known sites of nearly 300,000 horsepower, of which about 100,000 horsepower is developed.

The chief streams are the Mississagi, the Spanish, the Aux Sables, the Onaping, the Wanapitei, the Sturgeon and the French rivers.

Tributary to Lake Superior are water-power streams with an aggregate potentiality of about 300,000 continuous horsepower. About half of this total is on the Nipigon river, on which an initial development has been made for the municipalities of Port Arthur and Fort William by the Hydro-Electric Power Commission of Ontario.

Important Power Site

The outflow from Lake Superior through what is known as the St. Mary river constitutes an important water-power site, which has been partially developed. In the extreme west of the Province, the English and Winnipeg rivers, which flow into the province of Manitoba, have important water powers; in Ontario these powers aggregate over 250,000 horsepower.

There remains to be mentioned the water powers of the streams flowing from Ontario into James Bay and Hudson Bay. The more important of these streams from the viewpoint of water-power possibilities are the Mattagami, the Abitibi, the Missinaibi and the Albany rivers.

The development of manufacturing industries in the Province necessitated the use of power. Ontario has no natural supply of coal and has required to import this necessity—both bituminous and anthracite—chiefly from the state of Pennsylvania.

The rising cost of this fuel and the fact that manufacturers were dependent upon outside sources for their supply, have been phases of the power situation in the province of Ontario which have greatly stimulated, and which doubtless will continue to stimulate, the utilization of the water powers of the Province along the lines of hydro-electric development.

The most important *early* hydro-electric developments, from the standpoint of magnitude and extensive transmission, is the plant at DeCew Falls. This plant takes its water from Lake Erie at the level of the upper reach of the Welland Canal at Allanburg.

Hamilton Was Objective

It is a high head development of about 50,000 horsepower capacity. The head developed is approximately 265 feet. Current is generated at 2,400 volts, 3-phase 66 cycles. The transmission voltage is 44,000 volts. The main objective of this DeCew power was the city of Hamilton, in the industrial life of which it has played a most important part.

It was in 1889 that negotiations by a group of United States capitalists were carried on with the Queen Victoria Niagara Falls Park Commission with a view to the development of power within the area controlled by the Park Commissioners. These negotiations eventuated in the formation of the Canadian Niagara Power Company —an ally of the Niagara Falls Power Company of Niagara Falls, New York

The nominal installed capacity of this plant, including a spare unit, is 121,000 horsepower. The ground was broken for the tunnel on October 4, 1890, and the first commercial power was delivered to the Pittsburg Reduction Company for the reduction of aluminum ore on the 26th of August, 1895.

The next important development at Niagara was that of the Ontario Power Company which commenced operation by the delivery of commercial power in 1905. This plant has its intake near the Dufferin

---

[*] Chief Engineer, Hydro Electric Power Commission, Toronto, Ont.

Islands above the falls. The water is conveyed a distance of over 6,000 feet by means of underground conduits, two of 18 feet internal diameter, and one, installed by the Commission as a war necessity, of 13½ feet internal diameter.

Made Original Contract

It was with the Ontario Power Company that the Hydro-Electric Power Commission made its original contract for 100,000 horsepower, the terms being $9.40 per horsepower per annum for power at 12,000 volts until 25,000 horsepower or more are taken, then $9.00 for all additional power supplied. The terms for power at 60,000 volts were $10.40 until 25,000 horsepower are taken, then $10.00 for all additional requirements.

In 1917 the Hydro-Electric Power Commission acquired the whole of the assets, including the generating plant at Niagara Falls, of the Ontario Power Company. This plant is now operated by the Commission.

In 1903, the Electrical Development Company entered into an agreement with the Commissioners of the Queen Victoria Niagara Falls Park whereby the Company was to utilize the waters of the Niagara river for the development of 125,000 electrical horsepower. The plant of the Electrical Development Company—now known as the Toronto Power Company—is situated above the Falls and about midway between the headworks at Dufferin Islands of the Ontario Power Company and of the Canadian Niagara Power Company.

Bought Assets in 1922

In 1922, the assets of the Toronto Power Company, including the development just described, were acquired by purchase by the municipalities of the Niagara district, and the operation of the plant of the Toronto Power Company was placed under the jurisdiction of the Hydro-Electric Power Commission.

From an initial investment in 1910 of some $3,750,000.00 the operations of the Commission have extended until at the present time it administers properties to the value of approximately $200,000,000.00, delivering upwards of 625,000 h.p. to fourteen different systems in various parts of Ontario, serving some 350 municipalities, the systems comprising some 3,500 miles of transmission lines.

Municipalities in the more newly opened up portions of the province of Ontario are, naturally, seeking opportunities for growth through the utilization of the natural resources tributary to them. The Hydro-Electric Power Commission is sympathetic to such development and stands ready, upon authoritative request from municipalities, to investigate and report upon the feasibility of new water-power development for the supply of communities desiring large quantities of electrical energy.

Ottawa First City

The city of Ottawa—the capital city of the Dominion—was the first municipality to receive its supply of electricity through the Hydro-Electric Power Commission.

In July, 1907, agreements were signed between the Ottawa and Hull Power Company and the Commission, and also between the Commission and the City of Ottawa, covering the delivery of electrical energy to the city of Ottawa to a limit of 2,500 horsepower. During 1910, this limit was reached, and in September of that year, the new contracts were signed increasing the load limit to 4,000 horsepower. This output was all required by February, 1914, when a third agreement was consummated, extending the limit to 20,000 horsepower.

The demand by the city of Ottawa has continued to increase and has now reached over 12,000 horsepower. In addition to serving the City, the Commission has extended its transmission lines for the purpose of serving a number of rural districts in the general vicinity of Ottawa.

We have now arrived at the place where it is proposed to describe some of the important features of the largest development in Ontario, in fact—the largest single electric development in the world, the Queenston-Chippawa installation.

In Service in 1922

The Queenston Chippawa Development, which was placed in service by the Commission on February 11th, 1922, is the latest addition to the Niagara System operated by the Hydro Electric Power Commission of Ontario.

True conservation in the use of the waters of the Niagara River for power purposes demands that practically the whole fall of approximately 327 feet between Lake Erie and Lake Ontario be utilized. The various power plants now operating at Niagara Falls vary in head from 130 feet to 210 feet, and with widely different degrees of efficiency.

The Queenston-Chippawa power development, the first unit of which was operated first in December, 1921, will have a normal operating head of 294 feet to 305 feet when the installation is complete. The conservation of head effected by the reduction of hydraulic losses to a minimum, and by refinements in the design of the various essential elements of the project as a whole, has resulted in the production of a power development which is believed to represent the best in modern engineering practice.

The plant in operation and in course of construction will consist of ten 60,000 H. P. to 65,000 H. P. 187.5 rev. per min. units, generating power at 12 kv., three-phase, 25 cycles, which in turn is transformed to 110 kv. for transmission with an ultimate capacity of 575,000—650,000 horse power.

Ice an Obstacle

On the Niagara River one of the great obstacles to securing continuity of service is the annual formation and flow of ice. Great fields of ice, formed in Lake Erie with its shallow bays and shores, are discharged down the Niagara River every spring, and at frequent intervals during the winter, under certain wind and temperature conditions.

In order to eliminate as far as possible interference of operation due to ice, a special form of intake has been provided.

The complete intake structure is approximately 1,100 feet in length and is made up of an entrance with lock gates for navigation, a bulkhead section, and the intake proper, the latter combining two forms of intake; the conventional or surface intake consisting of a concrete barrier or boom with fifteen openings each 18 feet in width, normally having eight feet of submergence, which submergence can be increased however by means of drop gates, to any amount up to the full depth of water or 35 feet; and the submerged intake consisting of gathering tubes or draft distributors, six in number and 675 feet in length.

A Sluggish Stream

For a great many miles above its mouth the Welland River is a sluggish stream, meandering slightly in a depression that can hardly be called a valley. The canal leaves the river channel near the crossing of the Michigan Central Railway and turning through a deflection of 28 degrees takes a course almost due north for over three miles.

The Control Gate is located at the upper end of the canal, where the earth section merges into the rock section.

This is the largest single leaf, roller type, motor operated gate ever built, and, before its installation was decided upon, an extensive study was made to determine the construction and operating economies in comparison with a two leaf gate with an intermediate pier.

Gate Motor Operated

The gate is motor operated by means of a worm drive connected to double hoisting gears on the top of the end towers. Roller chains pass over these gears connected at one end to counter-weights and at the other to the gate. The skin plate is riveted to the upstream face of the girders and beams, and consists of 7-16" plate which under full head is stressed to 11,000 lbs. per sq. in. The maximum stress in the rollers has been kept down to 625 lbs. per sq. in. the full diameter of the roller.

When the gate is raised to its full height it leaves a clearance of 14 feet above the water level in the canal, which will permit the passage of patrol tugs throughout the length of the waterway.

The total pull on the two chains in raising the gate is 316,000 lbs. The chains are made up of pairs of links, 9" x 1¼" each in cross-section, and rollers 4½" in diameter. The speed of lift is 4.6 feet per minute, thus requiring 12 minutes to operate the gate from closed to full open position.

Serves as a Dam

At the lower end of the forebay, and serving as a dam, is the screen house. This structure forms the entrance and the control for the penstocks. The entrance to each of the main penstocks is a modified bell-mouth consisting of three openings 12 feet 8 inches wide and 29 feet high at the rack supports. These three openings gradually converge into one opening 16 feet in diameter at the point of connection to the penstocks. Immediately behind the curtain wall, steel-lined gate checks are provided to support structural steel gates.

On account of the provision of Johnson valves at the lower end of the penstocks, permanent gates were not installed in the screen house at the entrances to the penstocks. Movable gates have been provided consisting of sectionalized leaves which can be dropped into checks in the piers by means of a travelling crane in the screen house.

The screen house, as constructed, provides for nine main units, a service unit and an ice chute, and is arranged so that a further unit entrance may be added at the north end.

The generating and transformer station is located below the escarpment and close to the river's edge.

Length to be Doubled

The structure required to house five main units and the service equipment is 350 feet long, and ultimately this length will be doubled. The substructure is of massive concrete construction carried down to rock foundations, and provides chambers and tunnels for housing and giving access to various kinds of apparatus. The superstructure consists of a structural steel frame work with reinforced concrete floors and roofs, and concrete, brick and tile walls and partitions.

The location of the transformer and switching portion of the plant on the top of the escarpment was considered, but owing to the difficulties in carrying the current at 12 kv. from the generators to the transformers up the cliff; and to operating advantages in having a combined station; also to the space between the generator room and the cliff being sufficient for the purpose, the decision was made to have the building to house the transformers and switching equipment combined with the generator room.

The steel columns are spaced longitudinally 26 and 24 feet alternately starting at the south end. The strength of the generator room steel was primarily determined by the necessity of providing cranes to handle the generator rotors which weigh about 300 tons each. The structural steel was so designed that it could be erected and the crane operated before the concrete walls were poured.

Guard Against Flooding

To guard against flooding due to the river level rising, the walls are designed to resist water pressure up to elevation 300, which is 16 feet above the base of the generators. No openings which might admit water from the river were permitted below this elevation, although temporarily a railway track is brought in at the south end and is protected by stop logs.

A 300 ton crane consisting of two separate units each having a capacity of 150 tons is provided in the generator room for handling generators, transformers and other apparatus. When the crane is to be used in lifting the generator rotor, which is the heaviest piece, an equalizer beam is used. This crane is supplied with a.c. motors and control.

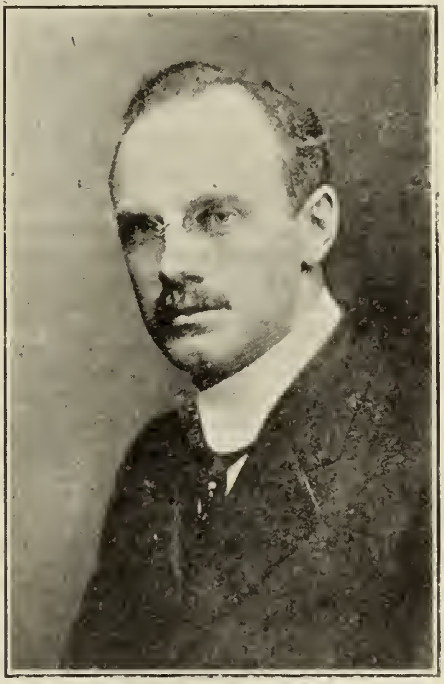
The entrance elevator, from screen house to entrance tunnel, operates at a speed of 450 feet per minute, and is equipped with a 25-cycle 550 volt, three-phase, variable speed motor of the commutator type with brush and shifting gear.

The main elevator in the power house is in the southerly portion of the building and serves all floors. It operates at a speed of 350 feet per minute and is equipped with a two-speed, 25 cycle, 550 volt, three phase induction motor. An automatic elevator located near the control room for the use of the operators, is also operated by a 25-cycle, 550 volt, three phase induction motor.

Nos. 1 and 2 turbines are designed for 52,000 H. P., and Nos. 3, 4 and 5, for 55,000 H. P., all at 305 foot head, the speed being 187-5 r.p.m. They are of the single runner vertical type set in spiral cast steel casings. The inlet diameter of the casings is 10 feet.

In Nos. 1 and 2, manufactured by the Wellman-Seaver-Morgan Company, of Cleveland, the casings are divided into nine sections with a separate speed ring, while in Nos. 3, 4 and 5, manufactured by the Wm. Cramp & Sons, Ship and Engine Building Company, of Philadelphia, the speed ring is case integral with the casings and the whole divided into 12 sections. The weight of the casing and speed ring in Nos. 1 and 2 is 240,000 lbs. while in 3, 4 and 5, it is 180,000 pounds.

The runners are made of cast steel in one piece, and provided with special renewable seal rings. Nos. 1 and 2 are 125 inches in diameter, and Nos. 3, 4, and 5 are 121 inches in diameter.



FREDERICK A. GABY, A.S., M.E.

The gate control is the usual double regulating cylinder typeope rating through rods to a shifting ring connecting to the individual gates through specially designed breaking links.

Made of Special Steel

All parts of the turbines adjacent to rotating elements, and to water passages subjected to high velocities are made of special steel and renewable. The main journal guide bearing on each unit is of the water lubricated lignum vitae type, such as has been used on all modern vertical turbine plants. This type of bearing was selected on account of its simplicity and low maintenance cost.

The governor actuator is set on the generator floor, the flyballs being driven by belt from the turbine shaft. The main valve is located adjacent to the turbine regulating cylinders, 35 feet below the actuator. To meet the conditions of this layout the pilot valve is hydraulically coupled to a small piston valve which is mechanically connected to the pilot valve of the main dog valve. The hand control stand is located on the generator floor and operates the regulating cylinders through the governor pressure system.

The governors are operated on the "Central" type of pressure system. Two motor driven centrifugal pumps, each delivering 500 Imperial gallons per minute, and located adjacent to two 3,000 gallon pump tanks built into the concrete substructure of the powerhouse, deliver the governor fluid at a pressure of 200 pounds per sq. in. to a header from which branches are connected to the governors through individual pressure tanks. The capacity of one pump is sufficient to operate five governors. An additional emergency pump is now being installed to operate the governor system in case of failure of the electric supply to the motor driven pumps.

The new pump will be turbine driven and will automatically come into service when the pressure on the governor system falls below a predetermined amount, by means of a specially constructed Johnson valve on the supply line to the turbine.

Does Not Corrode

The fluid in the governor system is filtered water in which a small amount of potassium bichromate is dissolved, the proportion being 7 pounds of potassium bichromate to 1,000 gallons of water. This fluid does not corrode the valve seats and has proven satisfactory in service.

The two service turbine casings are 30 inches inlet diameter, and the runner 42 inches outside diameter. The gate mechanism is of the "outside" type, similar to the main turbine. On account of the length of the shaft an intermediate guide bearing was installed. This bearing is of the oil lubricated type and furnished with a rotary oil pump, all arranged to be self-contained.

The governor is the "direct-connected" type, and the pressure liquid is ordinary lubricating oil. The flyballs are mounted upon the main turbine shaft, and the governor stand with self-contained pumping unit is placed on the turbine floor.

Furnish Quick Stop

A band brake is furnished in order to assist in bringing the unit to a quick stop when necessary.

A Johnson valve is located on each penstock near the entrance to the turbine casing. The action of this type of valve has been frequently described in other papers. The control of the Queenston valve is made through the operation of three small Johnson valves which automatically adjust the flow into the central and annular chambers so that the main valve plunger cannot travel at a dangerous rate.

The closing stroke is cushioned at the end, and in the opening stroke the plunger moves just sufficiently to permit the wheel case to be primed before completing its stroke. An emergency handle is located on the control stand on the generator floor by which an operator can close the Johnson valve in case of trouble. The valve can be opened only from the control located adjacent to the valve itself.

The present five units are each rated at 45,000 kv-a., 80 per cent. power factor, 12,000 volts, three-phase, 25 cycles at 187.5 r. p. m. They are capable of being operated continuously at 49,500 kv-a., with either voltage or current 10 per cent. in excess of the rated values. The type is vertical with direct-connected shunt-field commutating-pole, 250-volt, 150-kw. exciter.

Aid High Efficiency

The over-all efficiency of the generating units is slightly in excess of 97 per cent. at 80 per cent. power factor. The thrust bearing is designed to support a load of one million pounds which is slightly in excess of the weight of the rotor plus the hydraulic thrust imposed by the turbine. Upper and lower guide bearings are provided, the latter on account of the length of shaft and to keep the generator a self-contained unit.

The over-all diameter of these units is 25 feet, the diameter of rotor over pole faces being 18 feet approximately. The shafts are 30 inches in diameter in the guide bearings, and are provided with flange at lower end for bolting to corresponding flange on turbine shaft. The shafts are hollow with 8-inch diameter bore and are 30 feet 3 inches in total length. The over-all height of generators above the generator floor is 26 feet 10 inches, thus above the main floor only the top of the frame and the upper bracket, thrust bearing housing and exciter are visible.

The weight of the complete generator is 1,400,000 pounds, that of the rotor 615,000 pounds. The largest piece to be handled by the cranes weighs 600,000 pounds. Generators—45,000 and 55,000 kv-a.

A Partial Description

The foregoing is a partial description of the Queenston-Chippawa development, giving special attention to the mechanical features of this development. The first five units are now in operation and the other units are being installed as rapidly as possible, and when completed the Commission will have a generating capacity for the Niagara District of over 900,000 horsepower, including the Toronto Power Company and the Ontario Power Company plants.

The growth of the demand for "Hydro" service from the Commission is well shown by the following table:—

	Number of Customers			Total load for October	
	Urban Municipalities	Townships	Total Consumers	Ontario only (Horsepower)	Ontario plus exported power. (Horsepower)
1910	10	..	......	750	......
1911	26		......	15,214	......
1912	36		34,967	31,019	......
1913	51	7	65,689	45,502	......
1914	82	12	96,844	76,977	......
1915	112	18	120,828	103,959	......
1916*	166	25	148,732	167,661	
1917	179	34	170,916	266,214	333,399
1918	193	41	183,987	253,562	316,592
1919	208	42	216,086	262,281	328,175
1920	217	43	244,388	283,372	355,798
1921	236	44	265,000	305,247	375,010
1922*	250	97	335,000	553,000	628,000

*Central Ontario System purchased by Provincial Government and operated by the Hydro Electric Power Commission.
Ontario Power Company taken over by Hydro Electric Power Commission
*Toronto Power Company purchased by the Commission.

Realizing as it does the large amount of time—often several years—that must elapse between the initiation of a new, extensive water-power development and its being brought to the stage where commercial power can be delivered, the Hydro-Electric Power Commission has always been compelled to take early action on behalf of municipalities for the creation of new sources of supply for electrical energy.

It has sometimes required a good deal of courage on the part of the officers of the Commission to incur heavy financial outlay years in advance of the actual demonstration of markets to absorb electrical output, but, in no instance, has the judgment of the Commission eventually been found to have been in error.

Use Up Spare Power

At the present time, all evidences point to the fact that by the end of the year 1926, the present provisions made for the supply of electrical energy to Hydro municipalities will be fully taxed and no spare power will be available. The output of the Queenston-Chippawa plant will have been absorbed. The Commission has considered the possibility of producing further power at Niagara Falls, but the Chairman of the Commission, Sir Adam Beck, has stated from the public platform that he believes that it would be more profitable for all concerned to turn to the St. Lawrence river for the next large hydro-electric development.

It has already been stated that one of the basic principles upon which the Hydro-Electric Power Commission of Ontario operates is the furnishing of electrical energy to consumers *at cost*. Time and again, it has been stated—too often by those who knew practically nothing of the subject they were discussing— that the rates for light and power resulting from the efforts of the Hydro-Electric Power Commission were much less favorable than rates prevailing in other places. It remains, however, yet to be disproven that nowhere in the world over such extensive areas do communities and citizens obtain electrical power and light at such low rates as prevail throughout the Hydro municipalities in the province of Ontario.

And now, in concluding, I believe I have answered a question which may have arisen in the minds of many, namely, how does it come about that the operations of a new organization like the Hydro-Electric Power Commission of Ontario have attained such a phenomenal growth, and how has it been possible, so rapidly, to market such large supplies of electrical energy?

In a word, the secret lies in the fact that the Commission, as trustee and agent of cooperating municipalities, has sought to discharge its trust—and in point of fact has discharged its trust—so that the electrical energy has been made available *at cost* and then has been distributed to, and again vended by, municipalities to their individul consumers at *as near cost as possible*. Moreover, the Commission has made its distribution of energy to small municipalities and to rural districts, and the demand of these small municipalities aggregates a substantial load.

To sharpen dull and worn out files, lay them in dilute sulphuric acid, one part acid to two parts of water, over night, then rinse well in clear water. Put the acid in an earthenware vessel.

A method of detecting piston leaks is to place the engine on either centre and open the indicator cock from the opposite end from which the steam is being admitted. In this test, however, the steam valves must be tight.

A cylinder oil containing acid will probably cause pitting of the cylinder walls, hence it is advisable to watch the condition of cylinders after changing from an oil that is known to give good satisfaction to another grade.

Safety valves have blow down or huddling rings for adjusting the blow down. If a valve opens at the correct pressure, but does not close until the pressure has dropped, say, 5 lbs., instead of the usual 3 lbs., the huddling ring needs adjustment.

If the striking points of the piston against the cylinder head are not known, marks should be placed on the guide so that it can be clearly seen at any time that the piston has sufficient clearance at the end of the stroke, which should be kept equal at each end.

To cement leatehr to leather, soak ordinary glue or isinglass for 12 hours in sufficient water to cover it. Boil, and add pure tannin until the solution becomes sticky and has the appearance of the white of egg. The cement is then ready for use.

A crankpin will heat if it is not large enough to do the work, if good lubrication is not provided, if dirt gets inside brasses, if the brasses are not properly fitted, or if the brasses or pin are not of good material and in a smooth condition. Being out of line or keyed too tightly also causes it to heat.

Play Ball! U.C.C. of E. on Frolic Bent June 23

Members of Queen City Council, No. 27, to Drive Away Dull Care With Bumper Sports Program at Ward's Island—Be Sure to Be There

MEMBERS of the Universal Craftsmen Council of Engineers—"chalk up" an engagement on Saturday, June 23, that cannot under any circumstances be broken. For on that day at 2 p.m., or better still at five minutes to two, you must be at Bay St. dock, Toronto, with your wife and children, or if you are "unfortunate" enough to lack a wife, your best girl will do, to take passage to Ward's Island for the gayest frolic of the year.

Bring along your bathing suit, your running shoes, and the sunny side of your disposition, for with this crowd there'll be room for nothing else. Everything imaginable is on the program by way of amusement, and it certainly will be work for the judges to ascertain the various winners of the many contests scheduled by Queen City Council, No. 27.

For instance, when the staid married men are in line, braced and ready for the word "go," can't you hear twenty or thirty fond wives shouting encouragement to their better halves. and later when in turn the weaker sex prepare to run down the stretch, the shouts of hubby will differ only in that they will be a bit stronger, for everyone likes athletic honors to be kept in the family, and with so many families represented, —well, there's going to be some fun!

Chase Each Other

The bachelors and lonely single maids will also have an opportunity to see which one can do the chasing with the most success, and boys and girls and tiny tots will have every chance to show which one has had the most practice in running away, for everyone is going to take part in the races, and while all the ladies expected are, as Grand Worthy Chief Patton said at the anniversary banquet of Canada Council No. 27, flower-like, not one will be allowed to resemble in any way, a wall-flower.

The ladies are going to have a special blowing race, just by way of giving them a chance to do what their husbands and male friends do all the year 'round, and the men will have a measuring race. Mrs. E. M. Longmoor, chairman of the picnic committee, says she had to even them up to save argument! Power House will be responsible for a shackle race for the men, but not for any injuries which may be received, and the ladies can begin to practice up for for the spoon and egg race. The starter of these two races will be Arthur Murphy, editor of Power House, so he's the man to watch! And the crowning sport of all,—for the men!—will be watching the fair participants in the nail driving contest.

It is to be hoped there are a few ladies present who have had experience in hitting something on the head, for it is a case of reputation going before! However, when supper is ready at 6 o'clock, everyone will be in good trim to do it justice, and it is unlikely anyone will be burdened with "leftovers" to be consumed on Sunday.

Today we are learning a very old and simple truth all over again—the truth that the best way to make a living and to store up a competence is to get out among our fellow men and work for it. That method may induce brain fag and make muscles tired and sore, but if one goes at it right he is pretty sure to gain nightly the refreshing sleep that he needs. To many men—and women, too, for that matter—brains and brawn are out-of-date tools with which to carve a fortune.

Play Ball at Night

After the supper has been digested the sports committee will once more get everybody on their feet, segregate them evenly as to sprinting and throwing ability, and, oh, boy! we're off to a ball game with bells on. Why worry about a stiff arm in that old boiler room on the morrow, for here comes the ball and it's up to you to wallop it.

Among those who have promised to root for their favorites are, H. E. Terry, Past Grand Worthy Chief; L. J. Cudbird, Grand Trustee; Chas. L. Holmes, Worthy Chief; and W. J. Hudson, Secretary; Mr. and Mrs. A. M. Auchterlonie, Mr. and Mrs. Darbyshire, Mrs. Stephen and Mrs. Albert Baker.

The Program Follows

1. Tot's Race—Prize for each.
2. Girl's Race, 8-12 years—1st, 2nd, and 3rd prize.
3. Boy's Race, 8-12 years—1st, 2nd and 3rd prize.
4. Girl's Race, 12-15—1st and 2nd prize.
5. Boy's Race, 12-15—1st and 2nd prize.
6. Ladies' Spoon and Egg Race—Prizes given by Power House.
7. Men's Obstacle Race—Prizes given by Power House.
8. Single Ladies' Race—1st. and 2nd prize.
9. Single Men's Race—1st and 2nd prize.
10. Married Ladies' Race—1st and 2nd prize.
11. Married Men's Race—1st and 2nd prize.
12. Ladies Blowing Balloons—1st and 2nd prize.
13. Men's Measuring Race—1st and 2nd prize.
14. Queen City Officers (Past and Present.)—1st and 2nd prize.
15. Ladies Nail Driving Contest—1st and 2nd prize.

6 p.m. Supper.
Baseball.

The highly economical steam turbine must necessarily be operated condensing, but there are many cases where high steam economy is not the most important and the non-condensing turbine finds favor over the steam engine.

Bring along the little tots.

Burning Pulverized Fuel in Ford Motor Plant

By A. J. T. TAYLOR,* A.S.M.E.

Walkerville Installation to be Largest in Canada as Result of High Efficiency Effected at River Rouge With Boilers of 2,640 Normal H.P. Each

THE use of pulverized fuel as a step in fuel economy and high boiler efficiencies deserves a great deal of attention, and there is no single development in the matter of the utilization of Canadian coals that merits more careful consideration than the burning of coal in pulverized form.

This method of using fuel not only presents a means of obtaining results with the present available commercial fuels, but makes possible a still greater conservation of these fuels by replacing them with many of the lower grade fuels that are at present unsuited for burning by ordinary means.

It is now known that any of the coals native to Canada can be successfully burnt at a high efficiency in pulverized form regardless of whether they are the high sulphur coals of our Maritime Provinces, or the lignites of Saskatchewan.

Now Beyond Experiment

The literature on the subject of pulverized fuel is not abreast of the development of the art, with the result that it is not as widely known as it should be that the burning of fuel in pulverized form is now entirely out of the experimental stage.

The Ford Motor Company at Walkerville, Ontario, are at present installing a plant, which will be the largest pulverized fuel installation in Canada. The Ford Company have been pioneers in the matter of burning fuel in pulverized form, and their River Rouge plant near Detroit equipped with a pulverized fuel system is world famous, containing as it does some of the largest boilers ever built, these being 2,640 nominal H.P. each, and have on occasions been forced to a capacity of over 300,000 lbs. evaporation per hour.

The Oneida Street Station and the Lakeside Station of the Milwaukee Electric Railway & Light Company, and the Brunot's Island Plant of the Duquesne Light Company, have firmly and lastingly demonstrated to those responsible for the mechanical and financial success of those companies, and to their associated engineers, the economy to be derived from this method of fuel burning.

Confirms Conclusion

A further confirmation of the correctness of their conclusions, if such are needed, is evidenced by the action of such progressive engineering firms as McClellan & Junkerfeld, Sanderson & Porter and Dwight P. Robinson & Co., all of which firms are at present charged with the responsibility for large new utility projects, and each of them are recommending and installing systems for burning pulverized fuel for their clients under widely varying conditions of operation and fuel.

It would therefore seem unnecessary to bring forth further argument as to the work, reliability, adaptability or the dependability of the burning of fuel in pulverized form, which must be acknowledged with one exception to be the ultimate method of economically utilizing the full heat value of any available solid fuel.

The one exception is, of course, the process of low temperature distillation, wherein the lighter volatiles of the fuel are driven off at a relatively low temperature, and the residue pulverized and burned in suspension. Much thought and study is being given to this process at the present time, and it is expected that practical developments may be looked for in the near future.

Long, Expensive Study

In advocating the use of pulverized fuel, it should be definitely borne in mind that this is a special field of endeavour; that while the burning of coal pulverized and in suspension appears from observation of a correctly designed and properly installed system, much simpler than any other method of fuel burning, such simplicity of installation and operation was not achieved without long, difficult and expensive study and experimentation.

The development of one system required some seven years of intensive endeavour by an association of engineers of national repute, and the expenditure of nearly $700,000 to bring it to its present point of perfection.

As each pulverized fuel installation is made under widely varying conditions of load, fuel and operating conditions, each installation must be studied as a distinct engineering problem, and the work should only be entrusted to those who have shown by past accomplishment their knowledge of the subject, and ability to handle the several mechanical, physical and economic problems involved.

Demands High To-day

The present day demands for higher boiler ratings, the rapidly increasing demand for energy made upon most stations, the ever-present demand upon the Central Station operator for greater economy in meeting such conditions, make the accomplishment of the past five years in actual commercial installations an obligation upon the forward looking engineer to give his serious consideration to the advantages a change from his present method to pulverized fuel would effect. Where new stations are contemplated, it would appear that these advantages cannot be ignored.

Some of these advantages may be summed up briefly as follows:

First: The ability to burn any available fuel, either solid, liquid, or gaseous, in the same furnace without change, either simultaneously or separately.

Second: The ability to secure maximum evaporation per lb. of coal under all conditions.

Third: The ability to meet widely varying capacity conditions with any available fuel.

Fourth: The ability to maintain practically the maximum efficiency over a wide capacity range.

Fifth: The ability to instantaneously meet any sudden peak demands without later interruption to continuous service.

Sixth: The ability to bank over long periods with a minimum fuel loss.

The ability to burn any available fuel is of peculiar interest to Canada due to the widely varying qualities of coal which lie adjacent in many of our areas.

Gave Record Efficiency

The world's record for boiler plant efficiency has recently been made in Milwaukee where the system of pulverized coal burning gave during some tests an overall efficiency for the boiler, superheater and economizer of 91.3 per cent.

Pulverized fuel has now been so perfected that the cost of labor and handling complete (conveying, crushing, drying and pulverizing) together with wear and tear and depreciation is no greater than mechanical stoking.

It seems hardly necessary to add that where the size of the plant warrants the capital investment pulverized fuel has established itself as a commercially efficient system.

A self-contained engine is dependent upon its own frame to hold all of its parts together.

Adjust the catch plates on a Corliss engine so as to give them sufficient surface on their working edges, and they will wear longer. Also see that the working edges strike each other squarely. If the springs are weak, strengthen them by carefully pressing the ends towards each other in a vise, or get a new set of springs.

Upon taking charge of a new plant, do not begin by making promiscuous adjustments. It is better to wait a day or two until the apparatus is thoroughly understood, and then changes should be made only after the object to be attained is definitely known.

A right-hand engine is one the flywheel of which is to the right when looked at from the cylinder.

*President, Combustion Engineering Corporation, Limited, Toronto, Ont.

How to Save Millions of Tons of Coal Yearly!

By W. H. CASMEY*

Power Plant Engineers Find Want of Consideration of the Question of Excess or Insufficient Air Costly, Although Subject is Entirely Free From Complexity

TO WASTE coal at any time is proof we are not true to the trust we hold for future generations.

Combustion in its widest sense may be defined as the chemical combination of two or more substances, attended by the evolution of light and heat. For the purpose in view we have to consider the combination of "coal and air."

Coal is compressed mineralized vegetable matter. It contains from 75 to 90 per cent. of carbon, with varying percentages of hydrogen, oxygen and nitrogen.

Air consists mainly of a mixture of oxygen (21 per cent.) and nitrogen (78 per cent.); the remaining 1 per cent. consisting of elements and compounds in minute quantities which do not concern the power plant engineer.

Nitrogen is known as an inert gas—that is to say, it does not readily unite with other substances, and concerns us only as a diluent; it is the oxygen combined with the coal which results in the evolution of heat. The nitrogen becomes heated in passing through the furnace or fire, and carries away into the atmosphere a quantity of heat, which is definite loss.

Proportions Definite

Without going deeply into the chemical reactions which take place, it is necessary to point out that in chemical combination the elements uniting always do so in definite proportions.

In the case in point, it has been found that carbon and oxygen always unite in one of two proportions.

(1) If insufficient air is present, carbon monoxide is produced—C plus O equals CO. As this is capable of further combustion, it follows that its passage through the chimney to the air means a waste of fuel. Thus its detection in the flue gases is an indication that more air is required in the furnace.

(2) With the correct proportion of air one atom of carbon will unite with two of oxygen, producing carbon dioxide (carbonic acid gas) CO_2. In this case combustion is complete, for one atom of carbon will not unite with more than two of oxygen. The only effect of the introduction of too large a quantity of air being to cool the furnaces below the "point of combustion." This leads to imperfect combustion, smoke production, and, therefore, waste.

Indicator is Useful

It follows, then, that a "carbon dioxide indicator" will be as useful in assisting the boiler fireman in his knowledge of the conditions of his fires as are his steam pressure and water gauges for the internal conditions of the boiler. It is surprising so little has been done with this type of instrument, seeing it is the one positive method of knowing whether or not we are wasting coal.

The writer does not wish to infer the duty of a furnace, however, can be always accurately arrived at by a CO_2 indicator, for under certain conditions it may even lead astray.

Although the Editor does not entirely agree with the author's line of reasoning in this article, the practical conclusions arrived at by Mr. Casmey, after thirty years' practical experience with boilers and boiler users, must be heartily endorsed by Canadian engineers. The author's aim is to persuade all engineers in power plants in Canada to use for their own advantage the means placed at their disposal by the scientist; in other words, to bridge the gap between the laboratory and the boiler room.

For instance, if the air supply is too small for the weight of coal stoked, a high record of CO_2 is possible, but together with it there may be a small percentage of carbon monoxide (CO) which reduces the heat value of combustion indicated by the CO_2 readings. There is, however, but little danger of CO with a good draught and CO_2 readings in the neighborhood of 13 per cent.

The calorific or steam-raising power of coal is judged from the heat units contained per lb., one British thermal unit being the heat required to raise the temperature of 1 lb. of water 1 deg. F., so that to raise 1 gallon of water (10 lbs.) from 32 deg to boiling point (212 deg.) 1 180 B. t.u. would be required.

Calorific Value Low

One pound of good coal contains over 14,000, but for steam raising purposes coal with a calorific value of about 12,000 B. t. u. is generally used, but the writer has often tested boilers using fuel containing less than 10,000 units.

If coal and air are supplied in the proportion of 1 to 12, the resulting temperature will be 5,000 deg., which is much too high for steam-raising purposes; therefore it is good practice to allow 50 per cent. excess air, making the total required for good practical working 18 lbs. of air per lb. of coal, the temperature with this mixture being 2,700 deg.

It is want of consideration of the question of excess air for combustion which leads to the wastage of millions of tons of coal yearly, and yet the subject is so free from complexity that one cannot understand why, in a sense, general practice in the boiler-house is no better than during James Watt's life 100 years ago.

To burn 1 lb. of coal perfectly, 12 lbs. of air would be required. This would be 9½ lb. nitrogen and 2½ lb. oxygen. The latter gas, as already pointed out, would unite with the carbon. The gases leaving the furnaces would be 9½ parts nitrogen as before, but in place of oxygen we find 2½ parts, or say, 20 per cent. CO_2, the furnace temperature being 5,000 deg.

All Oxygen Not Used

If one pound of coal is burnt, allowing 18 lbs. of air, it will be found that all the oxygen will not be used, and the gases on testing will be found to contain 13 per cent. CO_2, the furnace temperature being 2,700 deg.

It is general practice to allow from 30 to 35 lbs. of air with each lb. of coal, and taking the minimum figure 1 lb. of coal and 30 lbs. of air, the CO_2 reading will be 7 per cent. and the furnace temperature only 1,700 deg., thus indicating that owing to the increased air supply of 12 lbs., a direct fuel loss of over 20 per cent. results.

When the temperature of a furnace falls below 900 deg. through the addition of fresh fuel, smoke will be produced and will continue until the furnace temperature is sufficiently high to ignite the gases.

During a black-smoke period each cubic of smoke is taking away two grains of carbon, and with 30 lbs. of air per lb. of coal—i.e., 390 cubic feet—780 grains or 11 per cent. of the coal escapes, and this could be entirely prevented by stoking when the fires are good, which is the only time they should be stoked.

A smoking chimney announces to the neighborhood that the man at the fires is either ignorant or neglecting his duty.

Color of Fires

It will be of service to firemen to know how from the color of their fires they can tell when getting good results.

Very faint red	977 deg. F.
Dull red	1,290 deg. F.
Dull cherry red	1,470 deg. F.
Red	1,650 deg. F.
Bright red	1,830 deg. F.
Deep orange	2,000 deg. F.

---

*Lecturer on Boiler Efficiency, The South Wales Institute of Engineers.

Clear orange	2,180 deg. F.
White heat	2,370 deg. F.
Bright white	2,550 deg. F.
Dazzling white	2,730 deg. F.

The 977 deg. would be secured with 47 lbs. of air per lb. of coal, the last temperature given, 2,730 deg. when the air suply was 17½ lbs.

The main causes of coal wastage in the production of steam may be summarized as follows:—

Area of fires too big for the gas outlets at the rear end of the boilers; fires too thin; stoking at the wrong time and often too heavily; fires given too much or too little air; boiler badly seated; leaky brickwork; boilers dirty inside; boilers and steam pipes exposed; damp and dirty fuel; lack of suitable proportion between grate area and chimney; heat in chimney gases.

In the manufacture of steel, iron, brass, or, in fact, any commodity, definite proportions of various ingredients are used, and the manufacturer is never in doubt as to the results.

Chaos Usually Reigns

In making steam, however, the cost of which is the foundation of practically all manufacture, chaos, as a rule, reigns, and it is the writer's object to place the boiler-house on the same common sense lines as any of the industries which depend upon it.

We know the temperature of combustion is constant—i.e., that a mixture of 1 lb. of coal and 12 lbs. of air produces a temperature of 5,000 deg.; also that when the mixture of coal and air is in the proportion of 1 to 18 the temperature of 2,700 deg. is constant, and that with every 1 lb. additional excess air the furnace temperature falls approximately 100 deg., so that when the coal and air are in proportion of 1 to 30 (which may be taken as general practice) the furnace temperature is only 1,700 deg., and since 1 square foot of grate at 2,700 deg. will radiate over twice as much heat in a unit of time as a square foot at 1,700 deg., the value of the smaller air supply as a means to economy is apparent.

Coal Saving Hints

To illustrate how a 2 to 1 radio or modified grate will assist in reducing coal consumption, let us take a 30 ft. x 7 ft. boiler. We find the ratio of grate to outlet is 4 to 1, so that to adopt the 2 to 1 ratio its gate must be reduced to 3 feet in length, its area is then 16.5 square feet, and consequently the air velocity through the furnaces is increased 750 feet per minute, and it can now burn if necessary 28 lbs. of coal per square foot of grate.

It is proposed to see, first, the cost of coal for producing the previous evaporations of 3,168 lbs., and then the actual boiler duty.

With a coal consumption of 40 lbs. per foot of grate thicker fires must be used than with 6-feet grates, and there is no difficulty in maintaining a CO_2 reading of 13 per cent. which equals an air supply of 18 lbs. per pound of coal, and assuming the gases leaving the boiler are 700 deg., as in the previous calculations the gases are, therefore, taking away 24 per cent. of the heat liberated, as against 39 per cent. with the longer grates.

By adding 8 per cent. for radiation and other losses the boiler efficiency may be taken as 68 per cent. which equals an evaporation of 8.4 lbs. per pound of coal; therefore, to give the previous evaporation of 3,168, only 387 lbs. of coal would be used, as against 462 lbs., or a coal saving of 17 per cent.

Evaporation Increases

By allowing the furnaces to burn 462 lbs. of coal, say 28 lbs. per square foot of grate per hour, the hourly evaporation of the boiler increases to 3,880 lbs., or nearly 19 per cent. more water for the same weight of coal burned on the longer grates; in other words, four boilers working with the 2 to 1 ratio will evaporate as much water as five similar boilers with standard grates, or will evaporate the same weight of water for 16½ cwts. of coal as the longer grates will do for 20 cwts., indicating a saving in fuel of 17 per cent.

There is money in carbon dioxide gas, and every consumer of fuel manufactures it as a by-product. The way to take the profit out of it is simply to produce as high a percentage of it as possible, and then let it escape up the chimney. That is all that is necessary—the profit appears immediately as a savings on the fuel bill. The only attention nedeed is to see that maximum production is maintained.

These results are quite understandable by looking even in a cursory manner over the factors brought into play; the shorter fires use less air, and the temporature of the furnaces will be approximately 2,700 deg., resulting in a more rapid transference of heat to the water, and added to this the ratio of heating surface to grate area is increased from 25 to 1 to 50 to 1. Thus the reason for the increased duty and efficiency becomes clear.

Having outlined his ideas so far as the boiler grates are concerned, the writer will now point out minor defects in the general practice of steam plants.

Fire 10 Inches Thick

A fire to be effective should not be less than 10 inches thick, it should be maintained at its maximum temperature, and this can be done by stoking it when at its best, for the liberated gases then quickly ignite and heat, instead of smoke, is produced.

To secure a smokeless fire stoking should be on the sides of the fire only and alternately—i.e., with two boilers a fireman should stoke the right-hand side of each fire, and after waiting a few minutes stoke the left sides—and by this means the required supply of hot air is provided for combustion.

If the fuel used is of the coking kind, the fireman should discard the drag or rake and use the poker only for allowing the air free access into the body of the fires.

The fuel should be kept as dry as possible, for damp coal not only minimizes the draught, but part of its heat has to be used for evaporating the moisture, and also for superheating the steam thus produced.

When mechanical stokers are in use, provision should be made for the clinker passing over a long deadplate behind the bars, as this enables a thicker fire to be maintained than is possible when the ash pit is close to the end of the bars.

Sweating Takes Place

Where the feed water entering an economizer is below 90 deg. F., and steam jets are used for producing draught, the gases become charged with moisture, and as their temperature is reduced below the dew point, condensation, or as it is generally termed, sweating, on the tube takes place, and this moisture gets under the soot on the bottom boxes and corrosion soon follows, especially when the fuel used contains sulphur.

The economizer, one of the most valuable helps we have outside the boiler, owes its birth and existence to our generally wasteful habits, and will continue to be needed until we learn to set, fit up, and stoke our boilers on more scientific lines.

If boilers are worked on the economical lines already indicated, the duty of the economizer is comparatively small, but for boiler plants such as the writer has recently seen, where over 30 lbs. of air per pound of coal were used, the economizers were doing nearly 25 per cent. of the total work.

Many steam users to-day are lulled into false security by the thermometer indicating the temperature of the water in the economizer as nearly equal to that of the steam in the boiler, whereas such a temperature is one of the best indications of wastage, since it can only be attained by the high temperature of the gases leaving the boiler, a condition not conducive to economy.

Others, again, are satisfied if the temperature of the gases at the chimney is low, the impression being that the low temperature is proof that the heat generated to the furnaces has been transmitted to the water in the boiler, and if all things are right, that assumption may be correct.

Detrimental to Life

As ebullition in a boiler can only take place above the furnace flues, the present practice of delivering the feed water into this section of the boiler is detrimental both to the life and efficiency of the boiler, since lime and other foreign matter in the water settles on the furnace flues and creates scale, which increases the cost of steam production and increases the danger of furnace flues collapsing.

Water is a poor conductor but a good carrier of heat, and it is, therefore, advantageous to deliver the feed water at or near the bottom of the boiler, and by fixing a suitable circular over the fireboxes where rapid ebullition takes place, a motion parallel to the boiler flues is given to the water, thus distributing the heat, with the result that ebullition is maintained the full length of the boiler.

The value of equal distribution of the heat inside of a boiler is very great, as a flue when covered with water boiling rapidly will transmit about 50 per cent. more heat per unit of area than when the water is stagnant, free circulation is, therefore, a factor in favor of coal economy.

Cut Heat Losses

Division walls between boilers should not be less than 16 inches thick, with a 2-inch cavity in the centre filled with flue dust, and all external walls should befitted with a similar dust cavity, the effect of which is to reduce to a minimum heat losses through the brickwork.

Along the centre of each furnace flue a 4½-inch brickwork wall should be erected, starting 4 feet behind the bridge and continuing for 15 feet, and along the centre of the bottom flue to within 6 feet of the front end of boiler, a midfeather 9-inch wall to be built to within 3 inches of the boiler plates.

The object of midfeather walls is to convert the carried heat of the gases into radiant heat, thus enabling the boiler to receive a larger share of the heat liberated than is at present possible; further, such heat accumulators neutralizes the effect of cold air passing along the flues during stoking and cleaning periods, and act in the same capacity to the furnaces as the flywheel to the engine.

Under normal working conditions about 18 per cent. of the fuel used by a boiler is used in banking up and restarting the furnaces, and where the brickwork walls are in use part of the heat taken up by the brickwork during working hours is given up to the boiler during meal-times or through the night. In several cases known to the writer the firemen, since the introduction of these heat accumulators, commence work at 5.50 a.m. instead of 5 a. m. as previously, since they find the steam near blowing off on their arrival, forcing the fires is thus not necessary, and economy is affected.

Chimney Vital Factor

The cost of natural draught varies from 10 to 25 per cent. of the value of the coal used, the chimney is therefore, one of the factors to which the coal economist should pay careful attention. The general boast of the steam user who has a good chimney is "I can burn anything in my furnaces. No fan draught can help me." Yet the truth is that the draught produced is proportional to the weight of coal wasted.

Induced draught is produced by means of a centrifugal fan placed between the economizer and the chimney, and in such a manner that by the changing positions of two dampers the fan draught or chimney only can be used as desired.

An induced-draught fan enables the attendant to supply exactly the weight of air required for combustion. and thus secure a high furnace temperature, a smokeless chimney, and the maximum transmission of heat per pound of coal burned.

It is a common practice for three boilers under fan draught to give the same evaporation as four boilers with natural draught, as the rate of consumption is simply the measure of the speed at which the fan is running.

Overall Efficiency

The writer has seen many cases where the overall efficiency of the plant has increased from 7 to 10 per cent. after the adoption of fan draught, and such improvements are constant, not being effected in any way by atmospheric changes.

The more important conclusions to be drawn may be summarized as follows:—

The temperature of combustion is constant, but too high for steam-raising; but with a constant supply of air, say 18 lbs. per pound of coal, the resulting temperature is also constant, every pound of excess of air is directly or indirectly equivalent to an additional 1 per cent. loss in fuel.

A flame flued boiler gives its highest duty and efficiency when the fire-grates are not more than twice the area of the outlet for the products of combustion at the ends of the furnace flues.

Radiate Twice Heat

A furnace of 20 square feet area fed with coal and air in the proportion of 1 to 18 will radiate twice as much heat per unit of time as a furnace of 30 square feet area fed with coal and air in the proportion of 1 to 30.

The terminal temperature alone is no guide to a boiler's efficiency or duty, a boiler is giving the best results which has the greatest difference between its initial and terminal temperature.

As water is a poor conductor of heat, circulation should be made compulsory.

A chimney draught costs approximately 20 per cent. of the value of the coal used on the boilers.

To drive an induced draught fan costs 2 per cent. of the steam generated. Saving by induced draught not less than 8 per cent. and often more.

Heat accumulators in furnace flues and bottom flues are beneficial both to life and duty of boilers.

This does not by any means exhaust the subject, but indicates in what direction economy may be effected, and in conclusion the writer submits a few notes specially written for the assistance of stationary engineers in Canada.

For stoking a boiler, air is just as necessary as coal, and the best results are secured with 240 cubic feet of air per pound of coal, this mixture giving a furnace temperature of nearly 2,700 deg. F.

390 Cubic Feet of Air

In general practice 390 cubic feet of air, or even more, are supplied per pound of coal, and this gives a temperature of not more than 1,700 deg. The first-mentioned mixture in a well-set boiler and with good fuel evaporates about 10 lbs. of water, but the second less than 7 lbs.

If a furnace temperature falls below 1,200 deg. F., black smoke will be formed, and as each cubic foot of black smoke contains 2 grains of coal, by allowing 390 cubic feet of air per pound of coal, 11 per cent. is wasted during a black-smoked period.

A dull-red fire has a temperature of about 1,290 deg. F., but a white fire 2,500 deg. to 2,700.

Heat passes quickly through a clean boiler plate, but very slowly through a plate covered with scale; therefore, keep the boiler clean.

Economy in raising steam is secured when the furnace temperature is high, and the temperature of the gases leaving the economizer is low.

Do not use more than four shovelfuls at a stoking. Keep the bars well covered, especially at the back.

Do not let the steam gauge indicate when to fire, nor let the chimney tell the smoke inspector when the boiler has been fired.

Stoke when the fires are at their best, but never stoke when the chimneys still smoke, since this is a sure indication that the fires are not hot enough to ignite the gases, and more coals only make bad worse.

Do not keep the furnace doors open for any purpose longer than can possibly be helped.

Do not forget that a fire-grate 4½ feet long is more economical than one 6 feet long.

Do not forget to keep stokers clean and well oiled. Do not have the fires on the dead plates, for this burns the doors away and allows cold air to get over the fires.

Do not forget to brush well the brickwork of the side flues each time that the boiler is blown off for cleaning.

Do not have the water in the boiler above the ordinary working level.

Do not have any air leakages through the brickwork of the boilers or the economizer.

Finally, remember that the above suggestions are the outcome of practical experience, and if adopted will reduce work, save employer's money and give a purer air for all to breathe.

The turbine can be designed to operate on very low terminal pressures with comparatively slight increase of cost; its action as a heat machine is such that a greater expansion can be utilized and the economy is greatly improved by any increase in vacuum. When run non-condensing the turbine is less economical than the non-condensing engine.

One of the large heat losses incurred in the steam engine is that due to cylinder condensation, and one of the common methods of reducing it is to limit the range of temperature through which the steam is allowed to work in a single cylinder. For this reason simple engines are better adapted for low steam pressure, while compound and triple-expansion engines are advisable for high-pressure and high-temperature ranges, particularly if the load is uniform.

Rich Hydro Electric Possibilities in Quebec

By JULIAN C. SMITH,* M.E.I.C.

Present Rate of Increase Shows More Than Seven Million Horse Power Will be Developed and Utilized in Province in the Next Twenty-Nine Years

THE province of Quebec comprises that vast stretch of territory lying East of the River Ottawa and North of the United States boundary line, bounded on the North by Hudson's Strait, on the West by Hudson's Bay, and on the East by Labrador. The Province is 2,000 miles in width from the North to South, and 1,350 from East to West.

The northern section is for the most part uninhabited, but the southwestern portion lying along the lower part of the Ottawa and St. Lawrence Rivers, and extending south to the American border and east to the Saguenay River is an important and rapidly growing industrial section.

Topographically, the country north of the River St. Lawrence is divided into three great water-sheds; south of the river and west of the town of Levis, which is opposite the city of Quebec the country is a low lying fertile plain. East of the town of Levis the land rises gently to between one thousand and two thousand feet, with elevations of nearly five thousand feet in the Gaspe Peninsula. On this south side of the river there is no large waterpower as the watershed is comparatively narrow and although well watered is traversed by only a few rivers of any magnitude.

Drains Large Rivers

The north watershed is drained by many large rivers flowing into James Bay, and when the development of the country has progressed far enough to permit the waterpowers of these rivers to be utilized, enormous amounts of power will become available on the Nottaway, Rupert, East Main, and Kaniapiskau Rivers.

The east watershed is drained principally by the Hamilton River on which is situated a waterpower estimated at 700,000 horse-power at Great Falls, some 350 miles from the mouth of the river, and 200 miles north of the St. Lawrence River at the west end of the Anticosti Island.

The ultimate source of the water power of any country is the precipitation and the total potential water power produced by the precipitation may be estimated by calculating the potential energy of this precipitation in its descent from the high lands to the sea.

To calculate the total potential waterpower of the Province of Quebec we may superimpose a map of the precipitation upon a topographical map of the province and then divide the province into areas having the same average elevation and approximately the same precipitation. An estimate of the potential energy due to the precipitations can then easily be made. The precipitation in inches per year at different points of the province is as follows:—

Montreal—40.
Quebec—40.5.
Brome—34.3.
Father Point—33.58.
Shawinigan—37.61.
La Loutre—
Chicoutimi—30.
Anticosti Is.—36.

Julian C. Smith, the author of this article and president of the St. Maurice Power Company, Public Service Corporation, Quebec City; Canada Carbide Co.; Canadian Electric Products & North Shore Power Co.; vice-president and general manager of the Shawinigan Water & Power Co., consulting engineer and director of the Manitoba Power Co., has been appointed president of the Quebec Railway.

Half Energy Lost

While it is impossible to state accurately the percentage of energy lost before the gathering together of water takes place, it may be conservatively estimated at 50 per cent. on an average over the steep and shallow valleys that go to make up the different drainage basins.

As continuity of supply is an essential condition to all power service, due allowance must be made for the fact that while the precipitation is more or less equally distributed during the year, the run-off from the precipitation is unequally divided among the different seasons.

During the spring thaw the melting and running away of the accumulated winter snowfall produce flood conditions on all rivers and streams, raising the flow to as much as 20 to 100 times the minimum. The necessary waste of the greater part of the water reduces still further the quantity of energy which may be considered as available for industrial uses even under ultimate conditions of development.

Combining the sources of lost energy enumerated we may assume therefore that the actual potential electric energy of the Province of Quebec is approximately thirteen to fifteen millions of continuous kilowatts.

Cuts Power Available

In the present stage of the art of the development and distribution of hydroelectric power, only those sites near industrial centres and at which water power exists in considerable quantities are capable of being developed. The theoretical available quantity of fifteen to eighteen million kilowatts of continuous power must therefore be very considerably reduced in considering the quantity of power that is actually adaptable to industrial purposes.

From recent surveys of the waterpowers of the province, and considering only those rivers on which waterpower is available in such quantities and in such locations as could be economically developed either now or in the near future, the quantity of actually available waterpower in the province is estimated at approximately 5.25 million kilowatts of continuous power, of which some 800,000 kilowatts have now been developed and utilized. There remains therefore in the province of Quebec an available commercial waterpower about 4.5 million kilowatts of continuous power or about 12 million horse-power at 50 per cent. load factor.

The various amounts of power mentioned in this article so far have been described as continuous power, by which it is meant that the flow of water producing this power is sufficient to provide the full quantity of power twenty-four hours a day, three hundred and sixty-five days in the year, and I am now going to digress for a moment from the main subject of this paper to say a few words upon the subject of "Load Factor" or the proportionate duration of use of power.

Using "Load Factor"

It must be borne in mind that no industry is able to make continuous use of the power which it requires and therefore no power company supplying power for industrial purposes is called upon to supply the total amount of contracted power all day every day in the year. The term "Load Factor" is used as a measure of the duration of use of power and is defined as average power divided by peak power.

The load factors of different industrial loads in Quebec differ considerably.

---

*President, Quebec Railway, Light, Heat and Power Company. Extracts from a paper presented at the Annual Convention of the A.S.M.E. in Montreal.

For instance, power mills operate at a load factor of between 65 per cent. and 75 per cent. averaging more nearly 65 per cent., carbide and electro chemical plants operate at 85-90 per cent. load factor, cement mills 80 per cent. to 90 per cent. load factor, asbestos and mining industries 45 per cent. load factor.

The load factor of hydro-electric stations supplying various industrial establishments and providing power and lighting service to communities will obviously be the average of the combined load factors of the various loads. Such plants will therefore, not require to use continuously the flow of its water which will produce maximum output.

Providing sufficient water storage capacity exists, the surplus energy that the normal flow of the river could produce may be stored in the form of water, but otherwise a certain portion of the available energy which might be very great at certain seasons in the year must be allowed to run to waste. In estimating the amount of energy available for industrial uses from the flow of the river at a given head, due consideration must therefore always be given to the storage capacity of the watershed and to the amount of regulation of flow which is possible with full utilization of the storage capacity.

Increased Water Flow

In plants where no storage capacity exists, the installation of sufficient generating capacity to consume the increased flow of water during the six high water months becomes economically justifiable by the use of electric steam generators as an adjunct to the plant to make possible the utilization of the excess energy produced during these months by its conversion into steam.

The ability to obtain a return from all the energy available at all times of the year will make possible the development of many power sites, which is dependent solely upon the sale of continuous electric power as such, might remain undeveloped.

The earliest water power developments in the province were the old seigniorial mills constructed by the French Seignoirs, to grind the grain of their dependents. These mills were in existence as early as 1650.

These little grist mills were almost always developed by the construction of a small canal which carried the water to an overshot or undershot wheel where the heads used varied from about five or six feet up to ten or fifteen feet.

Built in 1895

The first hydro-electric development was the Montmorency plant near the mounth of the Montmerency River, seven miles below Quebec, built in 1895 and having an installed capacity of five 600 K. W. generators.

The two great developments existing to-day in the Province, are located at Cedars Rapids in the St. Lawrence River, thirty miles west of Montreal, and the developments on the St. Maurice River at Shawinigan Falls and Grand Mere. The third great power which ultimately may eclipse these is now being constructed on the Saguenay River just below the outlet of Lake St. John.

In addition to the above plants which generate electricity for use in public utility service or for industrial service in the neighborhood of power developments, there are a large number of hydraulic developments supplying power for grinding wood. These plants are widely scattered throughout the province, most of them having been built prior to 1910.

The total amount of hydraulic power used directly for this purpose in the Province, has been stated by the Water Power Branch to the 162,825 h.p.

With the advent of the vertical turbine and the increase in the size of electrical generating units, it became in many cases more economical to develop the power in the form of electricity to be transmitted to Pulp and Paper Mills constructed in favourable positions rather than to locate the mills at the site of the power development. The amount of hydro-electric power so used is stated to be 157,367 h.p., making a total of 320,193 h.p. of hydraulic turbines employed in the pulp and paper industry.

JULIAN C. SMITH, M.E.I.C.

Joins St. Lawrence

The St. Maurice River is a large tributary of the St. Lawrence, and flowing from the north joins the St. Lawrence at Three Rivers, halfway between Montreal and Quebec. The main power developments on the river are located at Shawinigan Falls and Grand Mere, twenty-one and twenty-seven miles respectively north of the city of Three Rivers.

The plants of the Shawinigan Water & Power Company are located at Shawinigan Falls, where the natural formation of the Falls furnishes an ideal location for power development. The available head is about 150 feet and after the dams and headworks had been constructed, the first two units in power house No. 1 of 5,000 h.p. capacity each, were put into commission in 1902. In 1909 the capacity of the station was 58,500 h.p., all the generators being of the horizontal type.

Power house No. 2 with two horizontal units of 18,700 h.p. capacity each, was in operation in 1911. Later three additional units of similar size were installed. The output of this station now totals 136,500 h.p., the latest unit put in commission in October 1922 being of the vertical type and having a rating of 43,000 h.p.

The water is carried to the turbine of the latest unit through a tunnel cut through the solid rock, while in all earlier installations of both power houses, concrete covered steel penstocks were used. At present the combined generating capacity of the two stations is 195,000 h.p., with provision for two more 43,000 units.

Operate Two Plants

The Northern Aluminum Company at Shawinigan Falls operates two power plants generating direct current for use in its own works. The total capacity of these plants is about 40,000 h.p., the units being of the horizontal type with each turbine driving two direct current generators.

At Grand Mere, six miles above Shawinigan Falls, is located the plant of the Laurentide Power Company. There is a head of about eighty-four feet and work on the power development was completed in 1916. The power house is built on the dam, and at present there are installed eight vertical units of 20,000 h.p. capacity each, with provision for one more unit.

The efficient operation at all times of the year of these hydro-electric developments on the St. Maurice River is largely due to the extensions of the Gouin Dam at La Loutre, two hundred miles above Shawinigan Falls. This dam is owned by the Provincial Government and creates the second largest storage basin in the world.

Serve City of Montreal

The Montreal Light, Heat and Power Consolidated, which serves most of the city of Montreal and surrounding district, besides taking a large amount of power from the Shawinigan Company, also owns and operates four hydro electric plants. The largest of these is located at Cedars Rapids on the St. Lawrence River about thirty miles above Montreal.

The plant is on the north side of the river, where a rock-filled dyke two miles long and paralleling the shore gives a headrace canal one thousand feet wide whose lower end terminates with the power house. The turbines operate under a head of thirty-two feet, and the present installation consists of twelve 12,500 h.p. and two 13,200 h.p. generators with four 1,500 h.p. water-wheel-driven exciter units. All units are of the vertical type.

The Montreal Light, Heat & Power Company also operates Soulanges plant, located on the St. Lawrence River about thirty miles above Montreal, with a head of fifty feet and an output of 15,000 h.p.; the Lachine plant at the Lachine Rapids, six miles above Montreal on the St. Lawrence, with a head of fourteen feet and twelve units giving an output of 13,000 h.p., and the Chambly plant on the Richelieu River, with an installation of eight units and a total output of 31,000 h.p.

The Quebec-New England Hydro Electric Corporation, formerly the Montreal Public Service Corporation, distributes power in the city of Montreal which is generated at its hydro electric plant at St. Timothee. St. Timothee is on the south side of the St. Lawrence River about thirty miles above Montreal.

Use has been made of a portion of the old Beauharnois Canal, which has been enlarged, and the drop due to the Coteau and Cedar Rapids is utilized to obtain a head of fifty feet. The plant was put in commission in 1911, and four 5,300 h.p. horizontal units are installed, giving an output of 21,000 h.p. The power is transmitted to Montreal at 44,000 volts.

Used as Reserve

At Hull, on the Ottawa River, the Ottawa and Hull Power & Manufacturing Company operate two hydro-electric plants. Their older plant of 10,000 h.p. capacity is now used as a reserve, depending on water conditions, while in their No. 2 plant there are two 10,000 h.p. horizontal units with the turbines operating under a head of forty feet.

The Southern Canada Power Company have a hydro-electric plant at Drummondville on the St. Francis River which is a tributary of the St. Lawrence on the south side. There are at present in operation two 3,350 h.p. units in the Drummondville plant with provision for the installation of two more units of similar size. The available head is 32 ft.

Construction Started

Construction has been started on several new developments during the last twelve months and the work is being actively carried on at the present time. Of chief importance, due to the size of the undertaking, is the project of the Quebec Development Co., on the Saguenay River.

The source of the Saguenay is Lake St. John, one hundred miles from its mouth, and the elevation of the lake is about 315 feet above mean sea level. Its watershed is approximately 30,000 square miles and the area of the lake varies from three hundred and twelve square miles at the extreme low water, to four hundred and two square miles at flood time. About 300 feet of the total drop from Lake St. John to Tidewater takes place within 25 miles and may be concentrated at two points. It is planned to develop 400,000 horsepower at the outlet of the lake, and 800,000 horsepower lower down the river; giving finally a total output of 1,200,000 horsepower. Work is at present proceeding on the 400,000 h.p. plant, which is expected to be delivering power in two or three years.

Develop Water Power

The Shawinigan Water & Power Company, through the St. Maurice Power Co., a subsidiary company, is developing the water power at the Gres Falls and La Gabelle Rapids on the St. Maurice River, six miles below Shawinigan Falls. By utilizing the total drop of the rapids and falls, which are close together, a head of sixty-five feet will be obtained, and four units of 33,000 h.p. each will be installed, giving a maximum output of 132,000 h.p., which will be fed into the Shawinigan Company's transmission system.

Another new plant upon which construction has commenced is the Calumet Island development of the Ottawa and Hull Power & Manufacturing Company. The site is near the town of Bryson, about forty-eight miles above Ottawa on the Ottawa River. When the dam is completed a head of 60 feet will be obtained and units will be installed to give a total output of 60,000 h. p.

There are certain difficulties which occur in waterpower engineering in this province, which meet engineers in every locality where the climatic conditions are similar to those which obtain in this latitude. Ice troubles in the past have caused serious interruptions of service and reductions in the available amount of power.

Two Broad Divisions

These troubles may be divided into two broad divisions:

a. Ice troubles occurring in the power house itself, due to the presence of ice on the racks on the waterwheels.

b. Troubles occurring in the water channels above or below the power house affecting the head acting on the turbine.

To a large extent the troubles in classification "a" have been overcome by better design of the power house and better knowledge of the cause of these troubles. By enclosing the rack structure and by getting the turbine chambers warm and in general by the use of larger units, much of the trouble which was experienced formerly, has vanished. The other trouble is more difficult to remedy, and inasmuch as the change of levels may be due to blockades of considerable area the remedy in most cases is peculiar to the power development.

Most plants on the St. Lawrence River experience variations in height of headwater or tailwater due to ice blockades at long distances from the power house. On smaller streams and particularly very small streams, these blockades may be extremely serious, as they may and do affect a large portion of the flow of the river.

Minimize Difficulties

In large power developments ways and means have been developed which minimize to a considerable extent these difficulties, and the expense of carrying out such efforts is justified in case of large plants where it would not be in a small one.

By keeping the channels open to permit the frazile ice to come up to the surface, and by the use of various skimming devices for keeping rid of this ice, a very considerable degree of success has been obtained at the Cedars plant on the St. Lawrence River. It may fairly be stated that while this ice difficulty was a serious menace some years ago, now such is not the case, provided the plant is a large one and has been located and built with the knowledge acquired from the operation of existing installations.

At the present rate of increase the total available amount of hydraulic power which is estimated at 5.25 million kilowatts or about seven million horsepower will be developed and utilized in the next twenty-nine years.

As the increase in the development will in general follow the increase in the population, the developments will increase at an increasing rate and the period before the development of all the power now in sight will be therefore considerably shorter than twenty-nine years arrived at by assuming a uniform rate of increase. A careful study indicates that in twenty to twenty-five years the seven million horse-power will be used up.

This time might be materially shortened if any large amount of power were exported from Canada.

ICE AND COLD STORAGE TRADES DIRECTORY FOR THE UNITED KINGDOM FOR 1923

Published by Iliffe & Sons, Ltd., London. Price $2.75.

The present edition has been revised and brought up-to-date, the addition of over six hundred new names in the alphabetical section, with the corresponding insertions in the classified trade section, necessitating an increase of 45 pages. Several new headings have been added for the first time, thus again marking the ever-increasing application of refrigeration to new branches of trade.

The directory is of great value, not only to those directly connected with cold storage and ice-making, but also to the many firms manufacturing requisites for those industries. A leading feature of the directory has always been the list of vessels fitted with refrigeration, and no effort has been spared in making it as complete as possible. In this section a large number of new vessels are included, while many former vessels have had to be inserted under new names owing to the assignment of certain ships to new owners under the reparation clauses of the Peace Treaty.

When the packing sticks in the stuffing-box of an engine, remove the flange, place the engine on the crank-end dead-centre and admit steam, which will blow the packing out on the rod.

Associations of Value

STATIONARY engineers in Canada are to-day reaching forward to careers of essential service to their employers, that is unmistakably the meaning of the phenomenal success assured the C.A.S.E. convention in Toronto next week.

Behind such a gathering are years of arduous work—a continual putting forth of effort on the part of a few to inspire the many to a realization of the opportunities for advancement in their profession and to a practical vision of what may be done to brighten the rather humdrum day in the average power plant.

Practical Work Best

IT is so much easier to learn how a thing is done than how to do it, that there is a great tendency at the present day to exalt academic instruction at the expense of practical training.

Boob work alone will never make an engineer, and much less will it teach the art of handling men which is so essential in the larger power plants.

From the university graduate in honors at one end of the scale down to the ambitious youth who puts a cross opposite the profession he would like to enter and then takes an advertised course of lessons by mail, no man can master the art of engineering without acquiring the most essential part of the knowledge by practical work in the boiler room.

On the Editorial Sea

PASSING events shape the editorial course, but the inspiration—the power to accomplish—comes when readers respond in no uncertain way to what they feel are right steps and commendable innovations.

The enthusiastic response that has come in the last few weeks from engineers throughout the Dominion has made this issue of Power House bigger and better in order to present in it a completely rounded exposition of the best in power plant methods.

Never forget for a moment that readers of the only Canadian newspaper devoted to the development of power for all industries, alone shape its course. Power House is published with the serious purpose of instructing and inspiring toward the best use of combustion methods, to reduce the cost of power generation and increase in a tangible manner the value of the operating engineer to his employer, a purpose which it must be admitted, needs constant revitalizing and inspiration.

This can only be obtained when every reader becomes an active member of the editorial staff, giving freely all his comments, suggestions, criticisms or approval.

The Fuel Demon Air

THE air demon is usually the cause of one of the greatest losses in a steam power plant. It may penetrate through a sudden crack or fissure in the fuel bed, and the up-to-date engineer must know where and why it entered because the answer directly affects his operating procedure.

He may ignore the air leaks which are always present around the breeching and uptake for minor losses beyond the point where the gases leave the last heating surface of the boiler itself can have little bearing on combustion problems.

Firemen are aware of the fact that coal doors must be open as little and as infrequently as possible. They understand that if they were left open between firings, or not closed instantly after firing, the steam pressure gauge would drop at once, and firemen are accustomed to running their boilers by the gauge—no matter what the cost. Yet although the destructive effect of cold air entering through the fuel doors is fully realized, the average fireman gives scant attention to this very same cold air when it enters through cracks and bare areas on the grates themselves and still less is he concerned over leaks in the brick setting of the boiler.

Prime Movers Report

THE report of the Prime Movers Committee of the N.E. L.A. this year took on a new form. It came rather as an abstract and a forecast than as a report. It is, however, possibly more informative and more enlightening to see what the committee believes to be of sufficient importance to spotlight.

All through its pages there is unmistakable evidence of a keen appreciation of the changes that are taking place in the central station, particularly in regard to furnaces and their relation to the boiler, to the introduction of air heaters, and to the realization of the absence of any real data of an up-to-date character on stacks and their construction with relation to the needs of the modern plant.

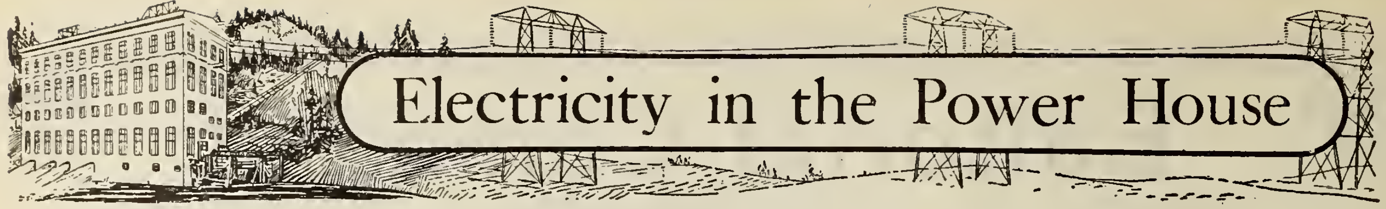
There is no mention of the super-power survey and it is evident that this subject is not looming as large in the minds of the industry as its romantic possibilities would naturally lead one to assume. However, time is an element in all such matters, and it may be that with the lapse of time, the thought of the industry will crystallize and become definite on the point.

Practical Knowledge Best

SCARCELY a day passes in which the engineer does not make some mention of B.t.u.—those little somethings that are produced by the burning of fuel and turned into useful work by the engine or turbine, yet, were the average engineer to be asked, "What is heat?" he would reply in words similar to, "Motion of the minute particles or molecules of the body."

The more learned would give a longer explanation, but the fact remains that its exact composition is a secret of nature just as much as electricity.

The engineer, however, does not need to know what heat is, but he must know how to produce steam economically. To be able merely to state that a B.t.u. is the heat required to raise 1 lb. of water 1 F. and that a pound of good coal contains about 13,500 B.t.u. is but one side; to be able to keep a boiler clean, to detect and stop infiltration of air through cracks in the boiler setting, to regulate the damper, to anticipate overloads and be ready with clean fires to meet them, will do more to keep down fuel costs than text book information.



Electricity in the Power House

WHY MOTORS STALL

In doing repair work in different shops not infrequently a motor would go bad and the shop would want an opinion as to the cause.

Invariably the symptoms were an apparent lack of power or a slowing up, lasting for days or weeks, growing worse, and then blown fuses and stalled motors. As the current used was a.c. and the motors all induction motors, there was never any chance of wrong connections or commutation troubles. When the motors displayed this lack of power, the first thing the operator would do would be to fill the oil reservoirs, to overflowing, of course. Actually this made matters worse because the oil that spilled over ran down the frame and on to the windings.

Dirt Causes Trouble

In every case of this sort we found that the trouble lay in dirt between the rotor and the laminations of the stator. This dirt was gummy enough to form a grip between these two close-working members and drag and drag, requiring the full power of the motor to turn it over light, without supplying any to the machine.

Taking the rotor out is the only remedy. Then its external metal surface is scraped free of the accumulation and washed with soda water. The inside of the coil ring is also thoroughly cleaned by scraping. As this gummy substance gets stuck to the coils too, it is a good plan to go over the coils as far as possible with a soft brush, dipped in the hot soda water, scrubbing off all the wires that can be reached. Whatever accumulation of any sort is upon the wires should always be cleaned off on general principles.

When the motor is assembled it will be found to turn "as free as water," and it will have plenty of power when hooked up to its load.

It is very easy to detect the kind of trouble mentioned, once you realize that the source of trouble is self evident.

Matter is Puzzling

With the gummy drag on the rotor, however, there is practically no indication of the reason for stalling and, unless one has been through it before, the matter is puzzling. The quickest way to determine it, is to throw off the belt or slip off the pinion and see if the rotor turns freely. If an otherwise satisfactory motor has blown fuses, it will be found that the rotor cannot be turned by hand, so great is the drag of the gum that has built up in that thirty-second of space between the two members.

Usually this trouble occurs where a motor is easy to get at and the operator is tempted to overdo the oiling. The excess of oil sticks and it travels slowly inward, aided by the fan action of the rotor and abetted by the dust of the room. The writer has found that motors well overhead in the dustiest of rooms were freer from this trouble than those in much cleaner rooms but in more accessible locations. —L. Thomson.

CORRECTING POLARITY

Four methods for correcting reversed polarity of direct-current generators are given in an operating code published this week.

The first method is applicable only to compound-wound generators which can be paralelled with one or more compound-wound generators of correct polarity carrying load. The equalizer switches of these machines, when closed, connect the inner terminals of the series field windings of two or more generators in parallel, equalizing the potential at these points and thereby causing proper division of the total load current among the series-field windings.

When the equalizer switches of all the machines in operation are closed and when the equalizer switch and the bus switch on the same side of the reversed machine are also closed, the series field of the reversed machine is placed in parallel with those of the machines in operation and so takes its normal share of the total load current.

Direction of Current

The current in the series field of the reversed machine is in the same direction as the normal operating current and thus tends to build up a field of proper polarity; if strong enough to overcome the residual magnetism, it will reverse the polarity to normal.

If this method fails to reverse the polarity, the method about to be described should be used. This method applies to shunt-wound or compound-wound generators when the bus can be energized from a source of correct polarity.

By this method, with the positive machine switch open and the positive shunt-field lead connected to the positive bus, current flows through the shunt field circuit, but not through the armature when the negative and circuit breaker and negative machine switch are closed. This develops a field of correct polarity in the field circuit, and when the machine is shut down the residual magnetism will be of correct polarity. Therefore, when the machine is again started up, it will build up with correct polarity.

Method of "Flashing"

When no source of correct polarity is available, a third method known as "flashing" may be used. In this case the shunt-field leads are reversed and the circuit through the shunt field is closed for an instant while in this reversed condition. This causes a wave of current to flow through the shunt-field circuit in the normal direction and of sufficient strength to reverse the existing residual magnetism. If the machine is then started up normally, the field will build up with correct polarity.

The fourth method is applicable to motor-generators which can be started from the direct-current end. This method is based on the fact that a shunt-wound or compound-wound generator of given polarity must be supplied with current of the same polarity in order to operate as a motor in the same direction. When current of normal polarity is supplied to such a machine, it re-establishes the normal polarity of the field and, consequently, that of the generator.

Convention Notes

The Universal Craftsmen Council of Engineers will hold its 21st annual convention in Rochester, N. Y., from August 7th to 10th. An elaborate program has been arranged by the Convention Committee in conjunction with the Ladies' Convention Committee.

Book Reviews

Doubleday, Page & Company have published for the Underwriters Laboratories a book entitled "A Symbol of Safety" which outlines the activity and functions of the company. Numerous illustrations show the nature of the experiments and research in testing materials and appliances used in fire and accident prevention.

The advantages of small, high-velocity steam piping are: Lower first cost for pipe, valves and covering, etc.; less erecting and maintenance cost; less weight; less radiation loss; less chance for water to accumulate and less difficulty with valves of smaller size.

The engine as a rule develops mechanical troubles with high superheat, especially where the steam valves have much travel under unbalanced pressures. The consensus of opinion seems to be that for slide or gridiron-valve gears a temperature of 400 to 425 deg. F. should not be exceeded, while the best point for the Corliss-type engine will be found below 450 deg. F. Above these limits lubrication is unsatisfactory and distortion of the parts is apt to give trouble.

Every-day Problems With Answers

Queries are invited on the every-day problems of all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped to solve a problem and a pleasure for us to pass on the data.

REPAIRING CROWN SHEET

The crown sheet in a locomotive type boiler used on the road was allowed to become dry for about one-quarter of its length from the front, resulting in a very noticeable sag around one stay bolt, causing serious leakage when steam was being raised. The leakage stops after the pressure reaches 50 lbs. but reappears when the pressure drops. The boiler has been in use about 8 years, operating at 150 lbs. pressure. Very dirty feed water has been used at times.

Would you advise lowering the pressure till the necessary repairs were made? Is the plate damaged and could a satisfactory repair be made by installing a new oversize staybolt?

Are boilers of this class inspected by the government when built at the factory?

In the gas engine h.p. formula given on page 28, December 5 issue of Power House, are the measurements for diameter and radius of pulleys and also the length of levers computed in feet or inches? —Roy J. Brodie, Forest, Ont.

Answer:—It is not possible to say whether or not the boiler would be dangerous, but it should be repaired at once. In all probability the plate has not been burnt so that putting in a slightly oversize stay bolt should make a satisfactory repair. It would be better to heat the plate by oxy-acetylene and drive the plate back to place before putting in the new staybolt, taking care not to heat the plate too locally. When putting in the new staybolt, allow it to project through the plate to hold a thin nut about the diameter of the stay, calking the plate tight around the staybolt before screwing the nut tight. This is done quite extensively with marine boilers.

All boilers in Ontario are subject to inspection by the Steam Boiler Branch of the Department of Labor when under construction.

In the gas engine formula in the Dec. 5 issue all measurements are in feet.

PUMP CAPACITY

One electrically-driven turbine pump delivers 538 gallons per minute through a 12-in. vertical pipe when another pump of the same capacity is delivering to the same vertical pipe, the combined discharge is only 958 gallons per minute. What capacity would three pumps give, delivering to the same pump against a head of 80 lbs.?—C. M. V., Nova Scotia.

Answer:—The discharge of 958 gallons instead of 1,076 gallons is due to the increased head against which the pump must work. The velocity of the water in the 12-in. pipe has nearly doubled, resulting in increased functional losses. The addition of a third pump would probably result in a loss of capacity greater in proportion than loss due to two pumps. The combined discharge of the three pumps might be between 1,200 and 1,300 gallons per minute.

CONNECTING TWO PUMPS

An electrically-driven turbine pump delivers 500 gallons per minute against an 80-lb. head, through a 12-in. vertical pipe. Is it practical to connect the discharge of a 1,000-gallon-per-minute pump to the same 12-in. line, running both pumps together? What would the combined discharge be? Is it good practice to use the same diameter pipes in the suction and discharge of a pump?

—C. M. V., Nova Scotia.

Answer:—If two pumps of the same characteristics are used, they could run together and the combined discharge would only be slightly less than 1,500 gallons per minute due to increased functional losses. On the other hand, if one pump had a flat characteristic and the other a falling, the combined discharge would be cut down considerably. It is a common practice to use the same size discharge and suction pipes on large pumps. A larger suction pipe gives only slightly less frictional losses, it is more important to keep sharp bends out of the suction cline. Many pump manufacturers use a taper connection on the suction and discharge of the pump.

THERMAL EFFICIENCY

How would you find the thermal efficiency of a boiler? —A. N.

Answer:—By subtracting the temperature of the gases at the uptake from the temperature of the furnace and dividing by the absolute temperature of the furnace. For example, what will be the thermal efficiency of a boiler having the temperature of the gases at the uptake 600 degrees and the temperature of the furnace 2800 degrees. Thus (2800—600, divided by (2800 plus 460) equals .6748 and multiplied by 100 equals 67.48%. This is the percentage of the heat that has been absorbed by the water in the boiler. The balance or 31.52% has been given to the furnace walls, settings and has passed up the stack.

CIRCULATION IN B. & W. BOILER

Explain the circulation of water in a B. & W. boiler.

Answer:—The circulation of water in a B. & W. boiler is from front to rear of steam drum, down rear tubes and headers thence through inclined tubes to front headers, up through front headers and into the steam drum.

FUSIBLE PLUGS

Where should a fusible plug be placed in the following types of boilers: (a) horizontal tubular, (b) vertical tubular, (c) locomotive, (d) Babcock and Wilcox.

Answer:—(a) On a drop pipe from the top of shell or in backhead above tubes. (b) In one of the tubes about two inches below lower gauge cock, a handhole being cut through the shell for the purpose of inserting the plug. (c) In the crown sheet. (d) In a drop tube through top of shell.

FUSIBLE PLUG

How should a fusible plug be constructed and of what material?

Answer:—The body is of brass, threaded, standard pipe size, or 1¼ in. The hole through the plug is made conical to prevent the fusible plug being forced out by the pressure; the large end of the cone should always be on the pressure side. The small end of the cone should not be less than ½ in. diameter. Banca tin has been found to be the most reliable metal to use for the cone, its melting point being about 445 deg. F.

PLUG MELTS WITH STEAM

Why will a fusible plug melt when covered with steam, and not melt when covered with water, all other conditions being the same?

Answer:—When a fusible plug is covered with water, the heat entering the plug from the fire is absorbed by the water; but when the plug is covered with steam, the steam will not absorb the heat entering the plug, owing to the fact that steam is only able to absorb heat less than one-third as rapidly as water.

CLEANING SINKS

What is a suitable solution for removing fatty substances from sink drains and sump pits? —Morton Mason, Rumford.

Answer:—A strong solution of lye would remove the fatty substance, but it is sometimes claimed the lye has a tendency to clog the pipes. If, however, after the lye has done its work, the pipes and drains be thoroughly flushed with water, no harm can be done to them.

LAYING UP BOILER

What precaution should be taken when laying up a return tubular boiler for any length of time?

Answer:—Blow out the boiler when warm and clean out thoroughly. If in a dry place leave off manhole and handhole plates. If in a damp place cover the inside of the boiler with black oil, remove all ashes and soot in direct contact with the shell of the boiler.

CUTTING IN BOILERS

What precautions should be observed in cutting in a boiler on a steam main which is under pressure; and when a boiler is to be cut out under the same condition?

Answer:—The steam pressure in the boiler should be brought up to the same as that in the main, all pipe connections should be drained and the by-pass, if any, opened to allow the pressure to equalize before opening the main valve, which should be opened cautiously at all times. To cut out the boiler the fire should be drawn off very low and the valve then closed.

BOILER BRACES

How do you find the number of braces required to stay a flat surface above the tubes of a boiler? —A Reader.

Answer:—By multiplying the area to be braced by the pressure to be carried, and dividing it by the area of the brace multiplied by the allowable strain per sq. inch. For exemple, the area to be braced is 955 in. and the pressure to be carried is 100 lbs. per sq. in. How many braces of the 1⅛" type will be required? The load to be supported will be 994 x 100 which equals 99,400 lbs. Now the area of an 1⅛" brace will be 1⅛ x 1⅛ x .7854 or .994", and allowing 7,500 lbs. per sq. in. the brace will be good for .994 x 7,500 or 7,455 lbs. Therefore 99,400 divided by 7,455 will equal 13 plus or 14 braces.

INSPECTING BOILERS

How would you prepare a boiler for inspection? —T. M.

Answer:—After allowing the fire to die out, and the boiler to cool enough to handle, punch out the tubes, remove all soot and ashes from beneath the shell and sweep off the heads and the shell. By this time the boiler will be ready to empty, open the blowoff valve, and remove the top manhole plate, and wash off the interior parts of the shell using a stream of water as hot as possible. Remove the lower plate and wash out the parts below the tubes, being sure to remove all loose sediment. Remove all plugs to the water column and feed pipe connections and disconnect the steam gauge for the inspector to test. If the boiler is of the internal firebox type, remove the grates.

BOILER INSPECTION

How would you make a general inspection of a Scotch marine type of boiler? —A. N.

Answer:—Look carefully about the seam for deterioration and pitting of the rivet heads of the furnace fronts by the action of the ashes; for pitting and corrosion at the bridgewall; for signs of leakage, broken rivets, pitting and corrosion at the joints or seams; for signs of pitting or corrosion at the fire line or about the grate bars; for leakage and crystallization of the tube ends, and fractures of the tube sheets; see that the uptakes are not burnt through and that the front connections are tight. Examine the interior of the shell to see that there are no signs of pitting or corrosion and that the braces are sound and taut. And finally look to see that the fusible plug is intact.

Personals

M. F. Trudel, superintendent of electrical energy of the city of Hull, P. Q., has formally tendered his resignation.

Hugh McNair, former gas engineer of the Manitoba Public Utilities Commission, has been appointed gas engineer for the Winnipeg Electric Railway Company.

Richard Allman, for several years first assistant engineer at Central Technical School, Toronto, Ont., has been appointed engineer at Riverdale Branch Technical School, appointment to date from Sept. 1.

WALTER J. FRANCIS, C.E., M.E.I.C.

Peter McMichael, managing director of the Dominion Radiator Company, was recently entertained at a banquet in the King Edward Hotel by Joseph Wright, president of the company, and the office staff.

A. R. Goldie, of the Goldie-McCulloch Co., Galt, Ont., was elected to the executive committee of the American Boiler Manufacturers' Association, at the thirty-fifth annual convention held at Hot Springs, Va.

F. W. Purple, of Tulsa, Oklahoma, constructions engineer and gasoline absorption plant expert, is now in Calgary, Alta., to take charge of the construction of the gasoline absorption plant to be erected at the Illinois-Alberta well. Work is being commenced at once.

Geo. Callard, the Montreal boiler setting specialist, who has been seriously ill at the Royal Victoria Hospital, is now convalescing. It will be some time, however, before Mr. Callard is able to resume work, as his physician has advised absolute rest for several months.

William S. Murray, Chairman of the Super-Power Survey Commission of the United States Geological Survey, in an address at the commencement of Lehigh University, on June 12, declared that "a saving of 158,000,000 tons of coal annually is possible by the utilization of the water now going to waste in the Niagara and St. Lawrence Rivers."

Walter J. Francis, C.E., M.E.I.C., has been elected to the office of president of the Engineering Institute of Canada. Mr. Francis was born in Toronto in 1872, graduated from the U. of T. in 1893 with the degree of C.E. His first practical work was assistant to the chief engineer in charge of design and construction, Toronto Union Station.

After engaging in many lines of engineering on his own account, he formed a partnership with F. B. Brown, which still continues under the name of Walter J. Francis and Co.

Mr. Francis has been actively interested in many of the large development schemes of recent years, one of these being his appointment to the position of consulting engineer to the Royal Commission appointed to make a complete report on the activities of the Hydro-Electric Power Commission of Ontario. This work has taken up the major portion of his time for the past twelve months.

Obituary

Frederick Grant, of the Incandescent Electric Light Co., Toronto, died at his home, 1291 Dundas St., West, Toronto, on May 25th, after a brief illness. Mr. Grant was formerly on the staff of The Toronto Globe as its engineer and later assistant engineer at the King Edward Hotel.

George Henry Ogden, mechanical engineer, connected with the Canadian Pacific Railway, died on June 2nd after several months' illness at his home in Outremont, P. Q. Mr. Ogden was a member of the Amalgamated Engineering Union.

Harry L. Shepherd died suddenly on May 31 at Simcoe Hall, Allandale, following a severe nervous breakdown. Mr. Shepherd was a graduate of McGill University in electrical engineering in 1900, and was for many years connected with the Allis-Chalmers Company, Toronto. Quiet, retiring and held in the highest esteem by his friends and acquaintances, Mr. Shepherd is survived by a widow and four children.

Practical Ideas From Practical Men

REMOVING CORRODED PIPE

Some time ago I had occasion to remove a pipe that leaked and was so corroded and burned that it was too weak to stand the pipe wrench.

I took a blunt cape chisel and hammer and bent the pipe in at the seams against the boiler shell, thus starting the pipe joint where it screwed into the boiler shell. Then I put plenty of thin oil on the portion of the threads that were dented in with the cape chisel. By turning the pipe back and forth as much as possible the oil was worked in on all the threads and the pipe loosened easily.

The use of oil prevents the unpleasant experience of breaking a portion of the threads off in the female fitting.

—C. F. Rye, Wesley College, Winnipeg.

HOW MUCH LUBRICANT

The flywheel test is the best one I know of for determining the proper quantity of oil to use in a steam engine. The test is very simple. Just pull out your watch and take the time required for the engine to come to a stop after shutting off the steam. The longer the stopping time the better.

It is plain that if a flywheel weighs, say, 2,000 pounds, it has a definite amount of energy stored in it when running at normal speed. Therefore, when steam is suddenly shut off, an equal amount of energy is dissipated every time the engine stops. With all conditions the same, then, an exactly identical length of time will be consumed in stopping every time the throttle is closed. By noting the stopping time every night and by altering the quantity of lubricant fed to the engine every day, the proper amount is in time determined.

The important thing is that external conditions must be the same every time the stop test is made. If the engine drives a belted machine, it is therefore best to throw off the belt and take the stopping time with the engine running unloaded. Under that condition longer time is consumed in coming to a stop and comparison of stopping times is made easier. In other words, the test is more delicate.

—W. F. Schaphorst, M.E.

STEAM BY-PASSES

There would be fewer accidents to large steam lines if by-passes were more often installed to heat up the main gradually instead of having to open the main valve, which is often done carelessly, allowing a large quantity of steam into a cold and perhaps badly-drained pipe, the result being a broken fitting caused by water hammer or too rapid expansion.

All proper precaution should be taken to prevent such accidents. The cost of installing by-passes on large steam lines is a good investment because it reduces the risk to life and damage to property. I known of one case where the fireman habitually uses a 24-in. trimo wrench in closing a 6-in. brass to brass-seated valve, closing the valve so tight that it is necessary to use the wrench to get the valve open. When I tried to make him realize the danger of such a proceeding, he informed me he had been doing this thing for the past five years and never had an accident, and that if there was any danger in his method it would have shown up long ago. Such men can only be convinced that such methods are wrong after an accident has happened to the equipment under their care.

Any person who is in the habit of visiting power plants will know that it is not uncommon for some employees to use long-handled wrenches in tightening bolts and nuts on large valve yokes and covers while high-pressure steam is on the line. This is a very dangerous thing to do. I was in a boiler room when the fireman cut in a boiler, one in a battery of five 66 in. x 16 ft. return tubular ones. He opened a 6-in. valve so rapidly that the vibration on the main shook the whole place and there was a rumbling noise like distant thunder. I was not glad that I was there.

Although the boiler could have been cut in by any capable fireman with no danger, a by-pass installation would have probably prevented any danger, for even an ignorant attendant will use a by-pass if it is there. When there is no by-pass he is liable to turn in steam much faster than safe practice calls for.

There are many cases on record where lives have been lost and much property destroyed through the careless handling of steam valves. Much of this danger would have been prevented if by-passes had been installed and used.

—James E. Noble.

TESTING STEAM TRAPS

The efficient operation of steam trap equipment is given varying degrees of attention by engineers. In one plant a card record is made of every trap, some 600 or more, and the history of the operation of each trap is maintained carefully. In another place a trap inspector is devoting all of his attention to steam traps. In other larger plants steam traps are given practically no attention, and so it goes.

Some engineers are very much interested in determining the efficiency of different types of traps and whether or not after a period of service they leak steam. Following is a method for testing traps for steam loss; the test is not absolutely accurate, for the radiation of heat to the atmosphere and other elements are not taken into consideration, but these are of minor importance. For a quick and approximately correct test the following will suffice.

To Explain Test

It might be well to explain the principle of this test. The water or condensate coming from a steam trap draining a line on a given pressure should contain not over so many heat units. Each pound of water is at a given temperature that will contain a given number of heat units.

The heat units in a pound of water at different temperatures and pressures can be obtained from the steam tables given in hand books.

In making the test the discharge from the trap is carried into a known amount of cold water of a known temperature. The test is conducted for an interval of time and at the end of this time the weight and temperature of the water is taken.

The original weight of water multiplied by number of degrees that the temperature of water is above 32 (temperature of water minus 32) will give the heat units in the water to start. A like computation will give the heat units in the water at completion of the test (degrees temperature minus 32 multiplied by total weight).

Gives Heat Units

The difference between the heat units in the water at the start and at the completion of the test will give the heat units added.

Now if it is found that the heat in the water that has come from the trap (the final weight less the original weight) is greater than that contained in an equal number of pounds of water at the temperature of the steam, then the additional heat represents steam loss and the trap is wasting steam. Take a quantity of water, 10, 20 or 30 lbs., or any number of pounds, and note the temperature as well as the number of pounds. Pipe the discharge from the steam trap into this water, well submerging the end of the pipe. Continue the test until the temperature of the water reaches around 100 degrees, stirring the water carefully to insure a uniform temperature, remove the container from the discharge and carefully note the temperature of the water, then weigh the water.

Use Table Provided

This test can be made by the engineer by following the directions given below and by using the table provided, which will show the increase in weight required for different pressures to indicate that the trap is not leaking steam. If a less amount of water is obtained, during the interval that the temperature is raised, than is given in the table, the additional heat indicates a steam loss.

Pressure	Increase in Weight	Pressure	Increase in Weight
5 lbs.	3 lbs. 2 oz.	120 lbs.	1 lb. 9¼ oz.
10 lbs.	2 lbs. 13½ oz.	130 lbs.	1 lb. 8¾ oz.
25 lbs.	2 lbs. 5 oz.	160 lbs.	1 lb. 7¼ oz.
50 lbs.	2 lbs.	250 lbs.	1 lb. 4 oz.

The following figures are from a test which will give the engineer a better idea as to the method of making the test and also how he may figure out the test for himself if he wishes to do so:

Steam pressure on trap—this must be actual gauge pressure—not a guess	100 lbs.
Quantity of water at start of test	10 lbs.
Temperature of water at start of test	60°
Heat units in water at start of test 60-32 (freezing point) equals 28 degrees x 10 (amount of water)	280 B.t.u.
Quantity of water at end of test	11.70 lbs.
Temperature of water at end of test	100°
Heat units in water at end of test 100-32 equals 68 degrees x 11.7 (amount of water)	795.6 B.t.u.
Heat units added to water, 795.6-280	515.6 B.t.u.
Heat in 1 lb. of water at 100 lbs. pressure	308.8 B.t.u.
Weight of water at above temperature required to bring in heat found 515.6 divided by 308.8	1.66 lbs.
Weight of water actually discharged (11.70-10)	1.70 lbs.

Provide a pail containing 10 lbs. of water at a temperature of 60 degrees, arrange the discharge of the trap to enter the water in the pail, the end of the discharge pipe must be well submerged. Stir the water in the pail constantly until a temperature of 100 degrees is reached, then remove the pail from the discharge so that no more water from the trap will enter. Weigh the water and compare the increase in weight to the amounts given in the table under the pressure at which the test is made.

As the weight of water discharged was greater than that actually required to raise the water to the final temperature the trap does not leak steam.

—L. D. Goff.

STEAM TIGHT GASKETS

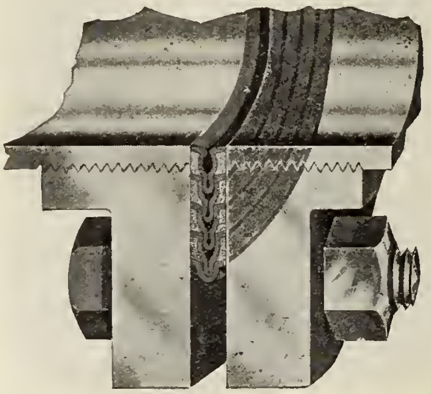
The writer has read with great interest the letter by James E. Noble in the May 5th number of Power House, page 34, in which he criticizes a few of the statements made in my article, "Practical Gasket Hints," which appeared on page 31 of the April 5th issue of Power House.

Regarding the thickness of sheet rubber or combination rubber and asbestos gaskets, the writer does not deny that such gaskets should be made as thin as possible. In fact, it has been aptly said that they should be made so thin as to have zero thickness.

In the writer's ten years experience with sheet gaskets he finds the combination of asbestos with steel in the form of a flexible metallic gasket is so far superior that there is really no comparison and as it is impossible to make a flexible metallic gasket thin and yet make it properly take care of expansion and contraction, this point becomes one that is hardly debatable. The writer does know that in his ten years of experience he has found the thick flexible metallic gasket to give far better service than the thin sheet gasket regardless of material.

Special Lengths Made

As for the length of wrenches, it is true that special lengths are made for certain kinds of work. Thus, a short wrench must necessarily be used, as pointed out by Mr. Noble, in places where a long handled wrench would be impracticable or impossible. However, it is easy to show that for every diameter of bolt there is a proper length of wrench, provided the bolt has a standard number of threads per inch, as most of them have. Where the number of threads varies the length of handle may also vary. Under no circumstances, however, should the wrench be so long that it is liable to stretch the bolt beyond its elastic limits or strip the threads with ordinary arm power.



Gasket.

Very good judgment must be used when tightening a bolt with a wrench that is too long. In this connection it might be interesting to readers of Power House to make note of the following which appears in Marks' Mechanical Engineers Handbook, regarding the sizes of wrenches in bolting up flanges:

Tests made by Crane Company show that a compression of about 12,000 lb. can be obtained by one man using a 16 in. wrench on ¾ to 1 in. bolts, a 36-in. wrench on 1⅛ to 1⅜ in. bolts, a 60-in. wrench on 1½ to 1¾ in. bolts, and a 72-in. wrench on 1⅞ and 2 in. bolts. Square nuts give from 20 to 25 per cent. less compression than hexagon nuts with a given effort on the wrench. Roughcut or uneven threads reduce compression 10 to 15 per cent. Lubrication of threads and bearing surfaces increases compression about 50 per cent. over that obtained with dry thread and surfaces. It is not necessary to overstrain bolts specified in the American Standard if proper wrenches are used, almost impossible to overstrain bolts larger than 1 in. in diameter. The following overall lengths of box wrenches are recommended (interpolate for intermediate sizes).

Size of bolt, in.	½	⅝	¾	⅞	1	1¼	1½	1¾	2	2¼
Length of wrench in.	7¾	9⅞	11½	13¼	15	19	23	27	30½	34

The above quotation, therefore, indicates that there is a proper length of wrench even for ordinary flanges with ordinary gaskets. With flexible metallic gaskets such as have come within the range of the writer's experience these wrenches may be used, but they must be used more carefully than where the old style thin sheet rubber or combination rubber and asbestos gaskets are used.

Using Extension Handle

True, where the wrench handle is too short, that is, shorter than standard length, the writer agrees with Mr. Noble when he says: "It is not bad practice to use an extension handle 6 or 8 inches long on a short handled wrench when tightening large bolt nuts."

Mr. Noble seems to doubt that a gasket can take care of expansion and contraction within a limited range. The writer is herewith sending an illustration of this modern thick flexible metallic gasket which clearly shows its construction. The gasket is made of a single piece of sheet steel which is bent so as to contain a sort of "U" at its center. It is then wound spirally beginning on the inside and building outward so that the "U"s dovetail one into the other with a layer of asbestos wound solidly between so as to form an impervious, strong, and at the same time flexible gasket. There are about 19 plies to every inch width of flange,

As for taking care of extremely long steam lines, without the use of expansion joints, bends, or other provision for expansion and contraction that always takes place in long lines, it would of course be ridiculous to make any such claims for a gasket that is only 3/16 or ¼ of an inch thick. It could be done if there was a sufficient number of joints, thus requiring enough gaskets to take care of the entire expansion.

Progress in New Power Equipment

A SINGLE PHASE MOTOR

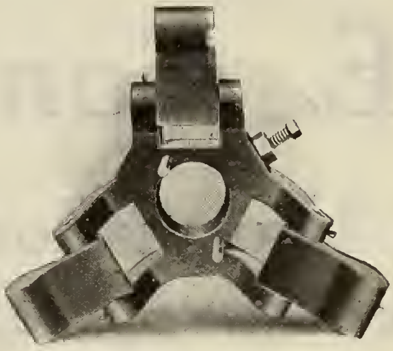
A new single phase motor that shows a distinct advance in motor construction, has recently been put on the market. It is not necessary to lift the brushes from the commutator and as a result the manufacturers have been able to use a short circuiting device that is simple and rugged.

The short circuiting device is composed of a disc built up of laminated copper and is held against the commutator with a high pressure; this pressure remains even when the motor speed has been reduced well below the normal full load speed; the resistance is consequently low and motor efficiency and output are not reduced by a material reduction in speed.

The short circuiting device is actuated by means of centrifugal weights counterbalanced and held from operating until the motor has reached the desired speed. With this arrangement the weights operate very rapidly and noislessly, giving an almost instantaneous short circuit.

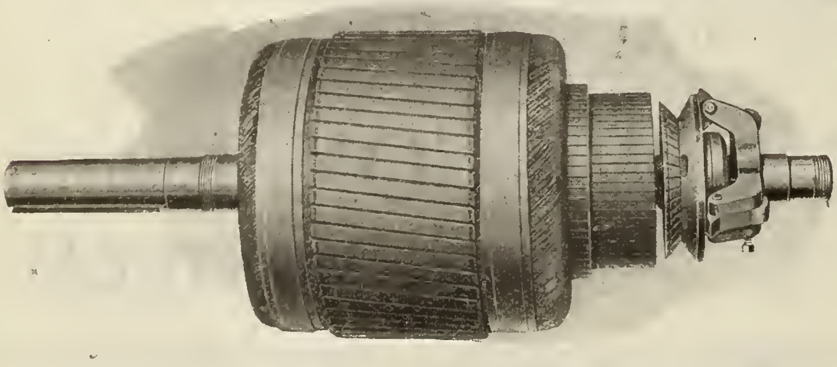
The brushes are in action only during the starting period, and after the motor has reached a pre-determined speed the short circuiting device short circuits every bar in the commutator, shutting all current from the brushes.

The device is so constructed that in its operation it has a wiping action against the commutator exactly similar to the wiping action present in the well-known circuit breaker. After the commutator is shorted the brushes rest on the commutator, but carry no current, and they have a polishing action which keeps the commutator in perfect condition and insures exceedingly long life of brushes and commutator. Under a recent test with stops two or three times a minute the motor was started and stopped 600,000 times. The only renewal necessary during this time was one set of brushes.



Simple motor governor.

Another feature of this motor, which is manufactured by the Canadian Fairbanks-Morse Co., Limited, is that ball bearings are used instead of sleeve bearings, and periodical oiling is not necessary. In addition, the fact that ball bearings do not wear keeps the rotor in the centre of the stator, eliminating failures due to the rotor striking the stator. A great many failures are caused by insulation failure due to oil; here again the new motor avoids this trouble by having its ball bearings packed in grease.



Complete rotor, showing commutator.

RELAY THAT THINKS

A "Relay That Thinks" is the term applied to a new relay invented by L. N. Crichton, design engineer of the Westinghouse Electric & Manufacturing Co. This relay, technically known as the Type CZ distance relay was described in a paper presented recently at a meeting of the Institute of Electrical Engineers.

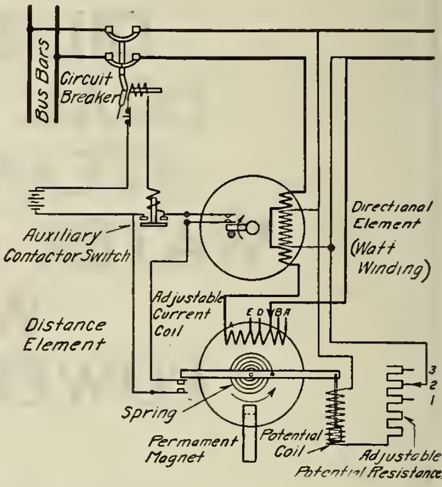
Mr. Crichton described in considerable detail the new relay, which has been called "the relay that thinks" because, when trouble occurs on a transmission system, it makes a calculation to determine the location of this trouble.

If close to the switching point, the relay will operate quickly to disconnect the disabled section, but if the trouble is some distance away the relay will operate slowly in order to allow any other relay which might be nearer to the trouble to act first. Because this device adjusts its time of operation to suit the location of the trouble it can be applied to almost any transmission or distribution system no matter how complex such a system may be.

The relay is of the induction type using many parts common to watt hour meters and resembling previous relays of this type in appearance. The new principle involved is shown in Fig 2. As shown in the figure, the current coil which is operated by the current in the main line revolves the disc which in turn tightens the spring.

Closes the Contact

When the spring is stretched it closes the contact and trips the circuit breaker, provided the voltage coil allows it to do so. This voltage coil is connected across the line so that if a short circuit occurs close to the relay with a consequent voltage across the coil it allows the disc to close the contacts instantly. However, if the short circuit is some distance away from the relay there will be voltage across the coil and therefore it will be necessary for the disc to revolve and stretch the spring enough to overcome the pull of the voltage coil before the contacts can be closed. This of course, requires some time since the speed of the disc is held down by the damping magnet.



Assuming that the spring must be stretched from point A to point B in Figure 2 before the pull of the voltage coil can be overcome and consequently the contacts closed, the time required to do this depends upon the speed of the disc which in turn depends upon the magnitude of the current flowing in the current coil.

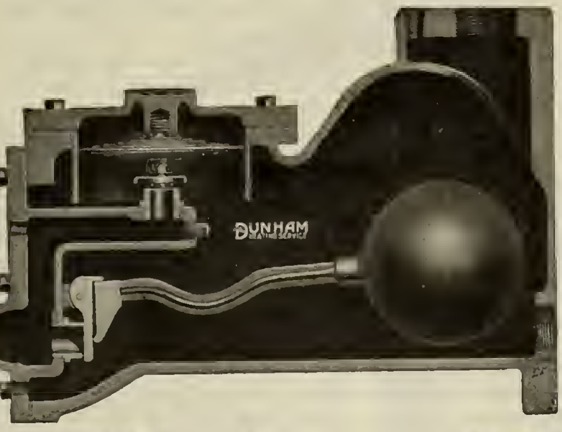
Since the speed of the disc is directly proportional to the current, the time required for the disc to move a given distance is inversely proportional to the current, or, treated mathematically, T varies as Ii. Also the space between A and B, and consequently the time re-

The DUNHAM
REG. TRADE-MARK
HEATING SERVICE

(Made in Canada)

Dunham No. 8 Trap

Automatically keeps heaters free from air and water without wasting steam. It has a wide application in many industrial plants.



This Heavy Duty Trap Serves Many Purposes

Dunham No. 8 Trap is unusually effective where steam condensation is great and where a large amount of air and condensate must be handled at all times. It is successfully applied to evaporating pans, large jacketed kettles, milk condensers, various types of blast coils and paper mill driers that operate under a vacuum and where the pressure does not exceed ten to fifteen pounds.

Besides the thermostatic disc there is a float control to handle large volumes of water and sudden calls for maximum duty. All metal is non-corrosive; mechanism positive in action.

Write for the Dunham Hand Book which describes this and other Dunham Heating Specialties.

MACLEAN STOKERS

MEMBERS OF THE C. A. S. E. IS IT NOT A FACT

that one of the biggest problems to-day is to maintain at minimum cost the exact head of steam to meet varying demands?

The MACLEAN STOKER takes care of this problem—automatically. It controls the feed, at the same time adjusts the air supply so that complete combustion of every pound of fuel is ensured.

Easy to install, easy to operate and costing but little for upkeep, the MACLEAN STOKER not only saves considerable labor but soon pays its cost by the coal it saves.

quired to lift the contact depends directly upon the force exerted by the holding coil, or in other words by the voltage across the circuit. This stated mathematically is T varies as E. Combining these two conditions we have T varies as E-i equals Z (impedance) which is equivalent to distance.

Geared to Wheel

The actual construction details of the relay are of course not those of the schematic diagram Fig. 2. but are more nearly like the view in Fig. 3. The main shaft of the relay is geared to a larger wheel which in turn tightens a spiral spring. This spring acts upon a lever arm which has the contact on one end and the voltage restraining coil on the other. The voltage coil is so designed that it will discriminate between voltages of very small value. For instance it will easily discriminate between zero voltage and 5 per cent. of normal voltage. It will also of course, withstand normal voltage continuously, and in order to assist in radiating its heat, cooling ribs are employed as shown in the illustration.

In order to eliminate the effect of residual magnetism the voltage core and stop are constructed of a special low hysteresis steel developed by Dr. T. D. Yensen of the Westinghouse Research Department. In order to minimize the effect of friction and other errors all moving parts are carefully jewelled and the actuating forces are much greater than is customary in other induction type instruments. For example the pull exerted by the voltage coil at full voltage is almost 1-2 pound and of course, the other forces must be in proportion.

Operates on Length

The relay is not adjusted to operate on a certain current and with a certain time limit as has been customary with present types but is adjusted to operate on the particular length of line to which it is applied. The current coils have a number of taps and the tap which is used determines the speed of the disc. Similarly the voltage coil is connected in series with a resistor having several taps so that its pull can be varied.

From the charts and curves furnished by the manufacturer the proper current and voltage adjustment can be made so that the relay will fit the particular section of line which is to be protected. Since the instruction book contains all the data for adjusting the relay, practically no calculations are required. In Figure 4 is shown a sketch of the time-distance curve for various adjustments of the relay.

A Relay that Thinks

The element which has just been described determines the distance from the short circuit to the relay, but it is also necessary in many locations to determine the direction of the short circuit. For instance, if a line loops through a substation it is important that the relay on each circuit breaker should be able not only to determine the distance of the short circuit, but should be able also to determine upon which side of the substation the short circuit is located. The directional element consists of a very sensitive contact making wattmeter of the induction type, which closes its contacts whenever its power is flowing away from the substation. These contacts are in series with the contacts on the distance element, and act as a sort of "check valve."

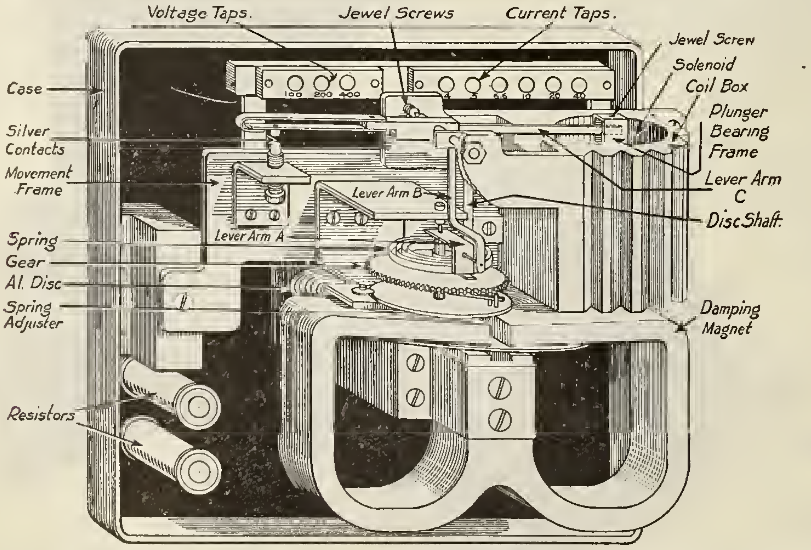
Whenever power is flowing into the substation, trouble is of course, not on that section of line, and therefore, the "check valve" prevents the distance element in series with it from operating even if it should desire to do so.

Directional Element

A schematic diagram of the distance relay equipped with directional element is shown in Fig. 5, and a general view of it with and without cover, in Fig. 6. The directional element is necessary at practically all substations and switching stations on any distribution system, but the distance element alone can be used at generating stations and other points where the power must always be flowing away from the bus bars under trouble conditions.

Some of the advantages of the distance relay claimed by Mr. Crichton are:

It does not require an excessive amount of mathematical calculations when applied to a complicated system. All dead short circuits will be cleared within one second and the majority of them in considerably less than that time; troubles on sections of line close to the generating station will be cleared just as rapidly as troubles on the more remote parts of the system; the breaker furthest from the trouble opens last, thus insuring the insertion of considerable impedance in the path of the short circuit before finally interrupting it which reduces the strain on the breaker and in effect converts every breaker on the system into a "resistance type" breaker; if trouble occurs on the bus bars in any switching station the relays on all the lines feeding power into this substation will open their breakers and thus kill the station in trouble without dropping any other loads; and, if for any reason the circuit breaker should fail to clear a section of line in trouble, the next set of relays in series with it would operate to clear the trouble and thus finally isolate the defective section.



Distance Relay - Type C Z

Power Notes

Owing to increasing business and the desire to be of greater service to its customers, the B. F. Sturtevant Company has long felt the need of a manufacturing plant in the middle west.

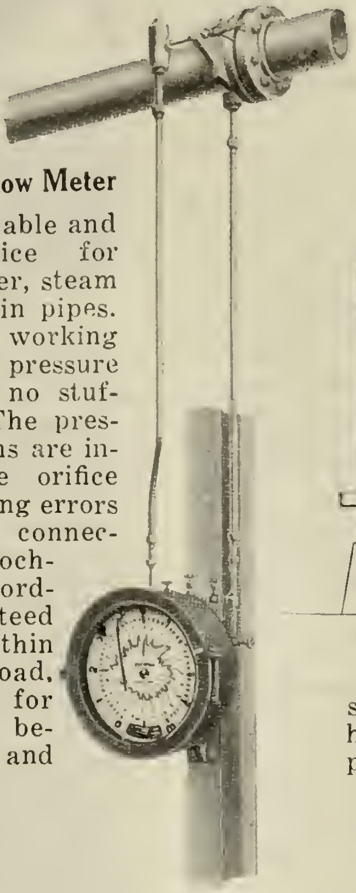
As almost every installation calls for specific engineering, it has been found difficult at times, to give full attention to this westward business from the big plant at Hyde Park, Boston, Mass., therefore, the Sturtevant Company has purchased the plant of the Wisconsin Engine Co., makers of Corliss Pumping Engines at Corliss, Wisconsin.

This new acquisition covers nearly ten acres and the buildings have approximately 150,000 feet of floor space.

A full manufacturing and engineering staff will be maintained and closer co-operation given to western customers. Shipping raw material east and the finished product west, adds a good

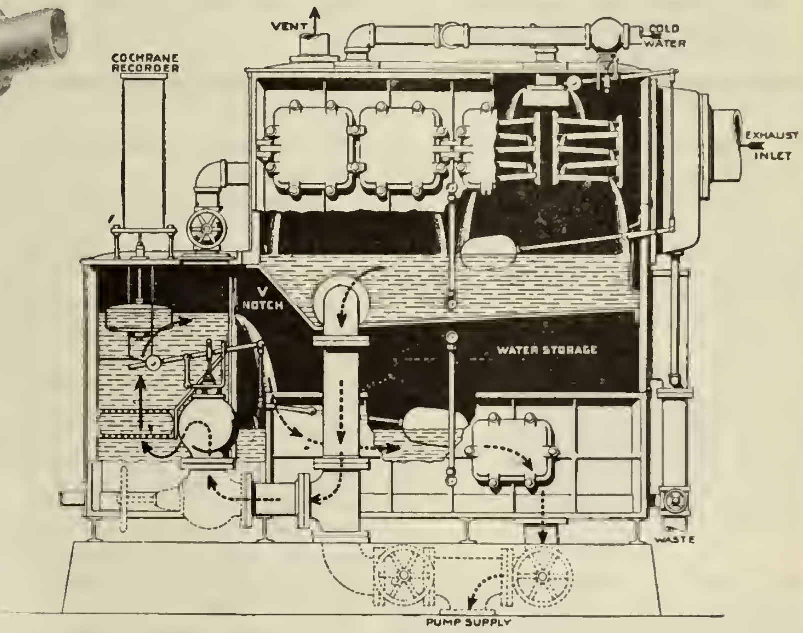
"TO ECONOMIZE—COCHRANIZE"

Let us show you how the Cochrane Equipment Will find and stop waste in your Boiler Plant



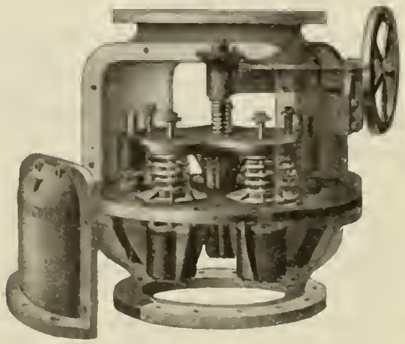
The Cochrane Flow Meter

is a simple, reliable and accurate device for measuring water, steam or air flowing in pipes. There are no working parts in the pressure chambers and no stuffing boxes. The pressure connections are included in the orifice plate, eliminating errors from faulty connections. The Cochrane Flow Recorder is guaranteed accurate within 1% of full load, plus or minus, for flows ranging between 20% and full load.



The Cochrane Metering Heater

saves coal by heating the feed water and helps save coal by telling whether or not the plant is being operated economically.



The Cochrane Multiport Back-Pressure Valve

differs from the ordinary back-pressure valve in that a number of small disks are used instead of one large disk, thus reducing the size, weight and travel of the disks. The back pressure can be controlled from a distance. The Multiport is built in all sizes for vertical, angle and horizontal pipes, also with provision for water-sealing for vacuum service.

Without any obligation, may we send you combined catalogue No. 1080 illustrating and describing all Cochrane apparatus.

deal to the ultimate cost because of freight charge. The situation at Corliss will make a substantial reduction in transportation costs.

The new plant will be under the same direction as the other factories at Hyde Park, Galt, San Francisco, and Philadelphia with Ex-Governor E. N. Foss as president.

Harry W. Page has been selected as general manager and will be in entire charge of the Wisconsin plant.

For the past six years, Mr. Page was assistant general manager and was located at the main office of the B. F. Sturtevant Co.

The Canadian Fairbanks-Morse Company have recently supplied Nash pumps to the Rolland Ford Paper Company, the Spanish River Pulp & Paper Co., and the Donnacona Paper Co.

The Southern Canada Power Company have decided to proceed with the development of the power site at Hemmings Falls, P. Q., where it is planned to develop 30,000 h.p., for which the company have an immediate market.

The British Columbia Electric Railway Co., for further development of water resources, propose raising the total turbine capacity of the company from 52,000 to 268,000 h.p. at a total expenditure of $10,000,000.

The Canadian Fairbanks-Morse Co. have supplied to the Belgo Pulp & Paper Co. a 75 h.p. type "Y" crude oil engine for driving wood-carrying equipment at Van Bruzel.

The Great Northern Power Co. has selected June 23 for the official turning-on of hydro-electric power at their new plant at Indian Chutes, on the Montreal River. Officers and directors of the company from Toronto will attend.

The General Electric Company at Pittsfield, Mass., are said to have surpassed any previous accomplishment in high voltage, when on June 5 artificial lightning of 2,000,000 volts was produced in the high voltage engineering laboratory of their plant.

The Harris Abattoir Company, Keele and St. Clair Avenue, Toronto, recently suffered a loss of about $25,000 when a tank containing 9,000 cubic feet of hydrogen exploded in the generating plant.

Taylor Stoker Co., Ltd., have closed a contract with the Belgo Paper Co., Ltd., of Shawinigan Falls, for four type H stokers with steam power dump.

The Public Utilities Committee of Winnipeg, Man., have approved the appointment of Samuel G. Neiler, consulting engineer and steam heating plant expert, of Chicago, to make a report for the Winnipeg city council on the proposed central heating plant proposal fostered by the Hydro Electric System. J. C. Glassco, manager of the Hydro Electric in Winnipeg, recommended that the opinion of an outside expert be obtained to convince the council that the scheme was feasible and advantageous.

Announcements

C. S. Webber, of Page Hersey Tubes, Ltd., Toronto, was in Pittsburg last week investigating business conditions.

The Harland Engineering Co., of Canada, Ltd., are now located at 291 Mountain Street, Montreal, P. Q.

Letters patent have been issued incorporating Jacques Perron, Auguste Mathieu, Montreal, under the name of the Central Quebec Power Co., with a capital of $1,000,000.

The Lieutenant-Governor of Ontario has formally signed an order-in-council authorizing the construction of a radial railway from Port Credit to Oakville, Ont. The amount approved for the work is $1,065,667.

When the Canadian Electrical Association meets in Montreal, Friday, June 22, will be devoted entirely to those who have been engaged in the electrical business for twenty years or more. It promises to be a real event for the "veterans."

Moreland & Jones have opened a school at 755 Yonge street, Toronto, to prepare engineers for examinations of the second, third and fourth grades. Mr. Moreland is a mechanical engineer holding chief engineer certificates, and Mr. Jones is a marine and stationary engineer. This school offers a system of tuition, it is claimed, which is practical and includes illustrations of practical power plant operation.

Construction

The Hydro Electric Commission has been granted its application to construct turn-out switches at different points on the old Metropolitan Line, North Yonge St. This permission was asked in order to facilitate the handling of traffic.

The Hydro Commission have preparations under way for the construction of a $500,000 power development at Campbellford, Ont. The plans for the dam and power house have been completed, and work will be commenced as soon as the present dam and power house being built at Belmont Lake are finished.

The Nujol Laboratories, of Bayonne, N. J., have leased through J. H. Walker, of the Realty Service Co., Ltd., premises on Dufferin Street, Toronto, Ont. Machinery for the work to be carried is now being installed. The Wayne Pump & Tank Co. are also installing machinery in their new premises on Dufferin Street. Heretofore they have operated only a selling office under the name of the Canadian Pump & Tank Co.

At the spring meeting of The American Society of Mechanical Engineers in Montreal, May 28-31, the nominating committee presented the following nominees for the offices of the society. Election by ballot will be held in the fall. President, Fred R. Low, editor, "Power," New York City; vice-presidents, George I. Rockwood, president and treasurer, Rockwood Sprinkler Company, Worcester, Mass.; M. L. Cooke, consulting engineer in management, Philadelphia, Pa.; W. J. Sando, consulting engineer, Milwaukee, Wis.; managers, E. O. Eastwood, professor of mechanical engineering, University of Washington, Seattle, Wash.; F. A. Scott, president, The Warner and Swasey Company, Cleveland, Ohio; E. R. Fish, vice-president, The Heine Boiler Company, St. Louis, Mo.; treasurer, W. H. Willey, president, John Willey & Sons, Inc., New York City.

POSITIONS WANTED

FACTORY SUPERINTENDENT OR CHIEF Engineer is open for engagement. Have had wide experience in operating power plants and handling help in Canada. Apply Box 107, Power House.

REFRIGERATING AND MECHANICAL ENGINEER with 10 years' operating record, also with experience in heating and lighting work, desires employment in Toronto. Apply Box 108, Power House.

FOR SALE

BOILERS FOR SALE CHEAP—TWO 100 horsepower, 110 pound steam. Apply Box 102 Power House.

BURNHAM STEAM PRESSURE PUMP, 10 IN. x 1⅛-inch. x 12 in., nearly new, with Fisher governor attached. W. Ahearn, 538 McLaren St., Ottawa. When answering this advertisement please mention this paper. P.F.H.

FOR SALE—ONE 10 H.P. STEAM BOILER with base and 20 ft. smokestack; new flues and in A1 condition; also 1 steam turbine bottle washer and sterilizer; both in excellent working order. Apply Box, 103 Power House.

INDUCTION MOTOR — 220 VOLTS — 1800 r.p.m. 15 h.p.; single phase; can be bought cheap; write for particulars. Box 104, Power House.

I. H.C. 12 H.P. GAS ENGINE FOR SALE—ALL in good running shape, with 33-inch clutch pulley; will be sold reasonable on easy terms. Apply W. Harrison & Son, R. R. No. 5, Guelph. When answering this advertisement, please mention this paper. P.F.H.

TAYLOR SAFES FOR SALE—RARE OPPORTUNITY to secure a safe at small cost. They are in splendid condition. Inside dimensions and prices are as follows: 15" deep, 2 ft. 6" wide, 3 ft. 11½" high, fitted with built-in compartment. Price $250.00. 18" deep, 2 ft. 8" wide, 4 ft. 5" high, fitted with steel compartment. Price $200.00. Apply Box 10, POWER HOUSE.

WELDING

ELECTRIC AND ACETYLENE WELDING—of broken castings and machine parts, boilers, tanks, and marine repairs. Carter Welding Co., Ltd., 165 Adelaide West, Toronto. Adelaide 2841.

Why Fire Brick Can Never Rival Plibrico

HOW many times—when looking at a wrecked furnace wall--have you wished that the joints were as good as the brick? No furnace—regardless of the quality of fire brick used—can be better than its weakest joint. And therefore fire brick can never be made good enough to even rival jointless Plibrico.

Plibrico eliminates the joints.

This superior refractory comes to you in plastic form. It is pounded into any shape desired with a mallet, then trowelled smooth. Heat vitrifies it into a rock-like, air-tight, gas-tight lining that resists temperatures to 3100°F. Use it wherever fire brick can be used. Use it for front door arches, back arches, ignition arches, baffles. Wherever you put it it pays its way in longer, trouble-free service. Get the right start in ending furnace troubles by sending for "Modern Furnace Building"—the interesting 50 page story of Plibrico. It's free.

Plibrico is delivered only in steel containers of distinctive appearance, as shown below.

JOINTLESS FIRE BRICK CO.
1142 CLAY ST. CHICAGO

To the Delegates, Members and Friends who will attend the C.A.S.E. Convention at Toronto on June 25th to 28th, we most cordially invite you to visit our Booth.

We will have on exhibit the many articles which we manufacture in the rubber line, that are so essential to the engineer, consisting of a complete line of Mechanical Rubber Goods, including our specialties:

Daniel's P.P.P. Rod Packing
Ebonite Sheet Packing
Ebonite Valve Stem Packing

Make the exhibit of Quaker City Rubber Company your headquarters. Meet and chat with your friends. A cordial welcome awaits you at our Booth.

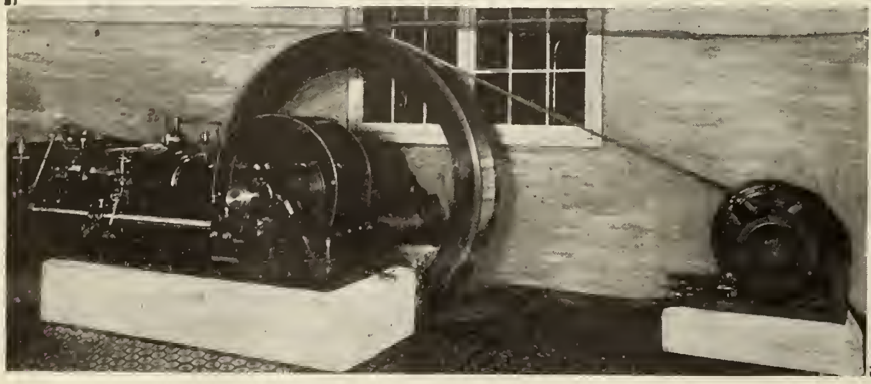
13 Years Constant Service Without Repairs



THIS cut represents one of our engines operating in the Mt. Albert (Ont.) electric light plant since December 23, 1910; nearly 13 years. The owner, Mr. Albert Dyke, says, "The main bearings have never been touched, not even tightened, and are still in perfect condition."

Catalogues of Heavy Oil Engines, Vertical Electric Sets, Pumping Sets, etc., mailed upon application.

QUALITY - SERVICE

The Hardest Test of a Feed Water Regulator

"Does it give correct feed on flash type boilers?"

The COPES System gives smooth regulation even under the very difficult conditions imposed by flash type boilers, *because the* COPES *follows true water level, without lag*. It does not dance wildly up and down with the boiling hump.

When the load suddenly increases, the COPES temporarily cuts down the feed rate over the peak. When the load suddenly drops, the COPES increases the water input. Fuel savings of 2% to 8% are recorded.

The action of the COPES is positive, certain, "trouble-proof"—because of its simplicity. It has no springs or diaphragms, no floats or displacement members—just a sturdy expansion tube and a balanced valve. And in actual test, COPES Regulation has proven accurate to 1 5 of 1%.

Write for Catalog D, explaining why nearly all important power plants use the COPES.

STERNSON SERVICE

No Mystery—Just Chemistry

You Are Cordially Invited

to see our
exhibit at the

**C. A. S. E.
CONVENTION
June 26, 27, 28**

The basis of most expensive boiler compounds is nothing but Silicate of Soda, which, properly graded, will remove and prevent all boiler scale.

BOILER BRAND—This is but one of our many grades of Silicate of Soda. Its action is similar to the most expensive boiler compound on the market. Why buy high-priced compounds with fancy names?

STERNSON No. 30—A high temperature cement which ensures permanent joints in your furnace and protects your brick at the weakest spots—the edges. Withstands up to 3,000 deg. F. Comes ready for use.

STERNSON No. 40 MONOLITH—A plastic ceramic mixture which can be moulded by inexperienced workmen into a jointless, gas-tight furnace or fire-box lining. Not only solves all furnace troubles but is actually lower in cost to install than the old method of fire brick and mortar.

TRADE MARK

Nature's Water Softener
Copyright 1920—The Refinite Co.

For Boiler Feed Water

Refinite makes scale impossible. It takes out the scale-forming lime and magnesia before the water enters the boilers. You save not only fuel, but the trouble, time and expense of washing boilers and replacing tubes.

A coating of scale even 1-50 in. thickness wastes 100 lbs. from every ton of coal fired.

Write for Information and Catalogue.

Refinite Company of Canada, Limited
305 Continental Life Building, Toronto

TRIPLEX DRAFT GAUGE

Gives you accurate knowledge of furnace conditions at a glance. It indicates pressure in wind box, draft in furnace above the fire and draft in last pass.

It is designed and built for convenience of installation, maximum visibility and permanent accuracy. Each instrument must pass the Foxboro quality test.

Write for Bulletin CF-131.

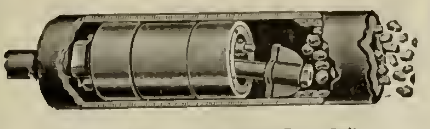
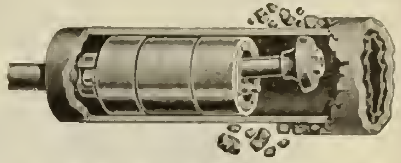
The **T. J. CUNERTY** *Company*
9 Richmond St E. Toronto.



Dean



For removing scale from Water Tube Boilers.

Telephone : Adelaide 1135

For removing scale from Return Tubular Boilers.

You Are Paying for Coal You Don't Get Any Results From

Your boiler tubes may be more or less incrusted with scale. Let us handle your boiler scale problem. Every 100 lb. of scale wastes 200 lb. of coal every 10 hours of operation.

Get rid of the scale in a way that will not keep your boiler continually in a wasteful and unsafe condition.

This method of scaling boiler is recommended by the highest authorities on boilers in the province.

Let us either ship you a Dean Boiler Tube Cleaner on trial, give you a free demonstration in your own plant or Clean Your Boilers by Contract (distance no object).

30 years' experience Scaling Boilers—Over 100 references in Toronto. NIGHT, SUNDAY and HOLIDAY SERVICE.

There is Science In Belt Lacing

ALLIGATOR teeth penetrate lengthwise of the belt, leaving the long burden-bearing fibers intact. Each tooth clinches down over its group of fibers, compressing them so firmly that there is no internal friction and wear at the belt end.

The sectional steel rocker hinge pin is the only metal pin that avoids wear to the joint.

Keep these vital features in mind when you buy belt lacing, for the cost of any lacing is nothing as compared to the cost of the belt on which it serves.

Just a Hammer to Apply It
"Never Lets Go"

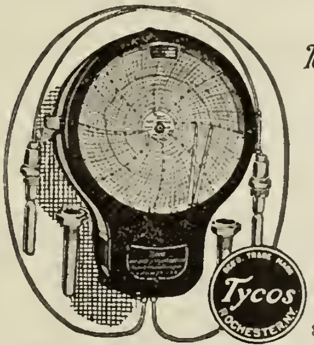
Tycos and Condensers

Performance is determined by the difference in temperatures at the inlet and outlet, provided the condenser is of the closed type. The *Tycos* Bi-Record Recording Thermometer is best suited for this application. It furnishes the operator with a chart showing the temperature at both points on one chart.

Where a record of the absolute pressure or vacuum created by the condenser is desired *Tycos* Recording Pressure Gauges are recommended.

Let us send you full information of *Tycos* Indicating, Recording and Controlling Instruments in the steam power plant. Ask for Catalog Part One.



Taylor Instrument Companies
110-112 Church St.,
***Tycos* Bldg., Toronto**

There is a *Tycos* or *Taylor* Temperature Instrument for every purpose.

Indicating, Recording and Controlling.

What is Boiler Scale Costing You?

Do you realize that one-eighth of an inch of scale increases coal consumption 36%; that expensive repair bills, shut-downs and other cost-eating factors are due in the majority of cases to accumulation of boiler scale? And it's so unnecessary because STEPHEN'S FEEDWATER TREATMENT not only removes all old scale, but prevents new scale from forming.

Stephen's engineers are men of practical experience. They can discuss your boiler feedwater problems in a practical way. Consult them freely at any time.

Stephens Chemical Mfg. Co., Ltd.
2004 Dundas St. W. -:- Toronto, Canada.

STEPHEN'S

Boiler Feedwater Treatment

Insures Safe Removal of Old Scale
Prevents Formation of New Scale
It Will Not Cause Foaming
It Does Not Vaporize Away
It Stays in the Boiler
Scale Stays Out

The Old Methods Expensive, Endangering Safety of Boilers

The New Method Economical, Re-assuring Safety of Boilers

Hays Improved Gas Analyzer.

Are You Wasting Fuel?

Numerous Canadian power plant men correctly answer that question by using the HAYS IMPROVED GAS ANALYZER. Rugged, portable, fast, accurate and INEXPENSIVE, it is the acknowledged leader of Flue Gas Analysis Instruments. Made in two styles. 3-chamber Analyzer for CO$_2$, O$_2$ and CO; 1-chamber Analyzer for CO$_2$ only. Stocked by Canadian Agents listed below.

HAYS DRAFT GAGES. "the fireman's compass," tell him how to regulate his damper, the condition of fires, baffles and settings. Write for your FREE copy of Jos. W. Hays' Treatise on "Drafts and Draft Regulation."

CURTIS ENGINEERING SPECIALTIES

Comprise a line of devices that have stood the test of years for the utmost in efficiency. They are built for dependable and enduring service. Scrupulous care in the selection of material and in construction, with adherence to the highest engineering standards, have won them a commanding position. The

CURTIS WATER-PRESSURE REGULATOR

will deliver water into service pipes at any desired pressure, regardless of any fluctuations of outside pressure.

Trouble with rust or clogging with sediment is prevented. Waste of water in domestic use by flying or spattering is avoided by the reduced pressure. This also prevents water hammer or concussion and prevents wear and tear on all packings and seats in valves and faucets, thus eliminating frequent plumbing bills. Adapted for use in pulp and paper mills, hotels, public buildings and dwelling houses. For ¾ in. to 2½ in. pipe, screwed. For 3 in. to 8 in. pipe flanged.

The Curtis Line of Steam Specialties contains many other notable devices. They are fully described in our No. 50 catalogue. Write for a copy.

JULIAN D'ESTE COMPANY
26 Canal Street, Boston, 14, Mass.

Emergencies Prove Its Superiority

It may not be often that the oil film fails in any of your bearings, but the possibility is always present. It is emergencies such as this that test the value of your bearing metals. Magnolia Anti-Friction Metal protects your shafts and bearings from damage in such temporary contingencies. With the lowest frictional coefficient of any known bearing metal—proven by U.S. and foreign government tests—it runs cool with less lubricant and is a safeguard against hot boxes and melting out where lubrication is neglected or may fail for any reason.

Try out a sample Magnolia-lined bearing and test its many advantages for yourself.

Why Individual Boiler Feed Water Treatment

Because the Condition of Each Individual Boiler Differs

We have demonstrated it to be the most successful method of freeing boilers of scale and stopping the further formation of scale-forming deposits or incrustations. Corrosion or pitting stopped at once by our scientific process which accomplishes the results desired.

"CLEAN ALL"

Indicates in a few words what the process does.

POWER HOUSE

Fostering Economy in the Development of Power for All Industries

Vol. XVI—No. 13. Published Semi-Monthly by The MacLean Publishing Company, Limited, Toronto, Ont. July 5, 1923

Power House, Point du Bois - View from Tail Race

Harnessing the Waters of the Winnipeg River

CANADA CEMENT CONCRETE FOR PERMANENCE

THE development of water power within economic transportation distance of Winnipeg has reached a point where 70,000 horse power is available, and there is sufficient additional reserve power to develop 500,000 h. p. when required.

At the power house site, the Winnipeg River falls over a series of rapids with a natural fall of 33 to 28 feet within a ¼ mile. This fall is increased to a total head of 43 to 48 feet, by a concrete dam; giving a pondage area of 7 sq. miles. The power house, completed in 1920-21 is of concrete and steel. The power house foundations, consisting, besides the series of draft tubes, of a series of flat tail race arches upon supporting walls tapered in plan, were built in pairs of arches; the two adjacent spans, built as a unit with a mid-wall, are resting upon asphalt painted skewbacks formed upon alternate tail race walls. The contraction joints are thus 56 ft. apart. By this means the use of reinforcing steel in these arches was avoided.

In the other elevation of the building the foundations were separated in three portions—arrester bays, the transformer and generator room and the turbine and rack rooms. This was done by the use of two vertical expansion joints, running the entire length of the building. Above the tail race arches, parting planes, asphalted and keyed with wooden strips, were provided in the main walls, with considerable success in the effort to avoid unsightly cracks.

This great plan of hydro electric development at Point du Bois has given Winnipeg power at the lowest rate on the continent, less than a half cent per KWH.

Interior and exterior of Provincial Paper Mills Plant at Mille Roche.

Provincial Paper installed "Jones A-C" at this plant, too---

YEARS ago, the Provincial Paper Co. installed two "Jones Standard" Stokers at their Port Arthur plant. The service given by these stokers was so dependable that since then the high-duty multiple retort "Jones A-C" has been installed in several plants.

At the Mille Roche plant, the two "Jones A-C" Stokers shown in the photograph opposite were installed in 1922. Mr. Imbleau says that operation is extremely satisfactory, the efficiency averaging 72% over all ratings. The boilers are equipped with the Craig Damper Regulator and the CO_2 never drops below 12%.

Provincial Paper, like so many other firms, installed the "Jones A-C" because they have found that "it pays for itself—then pays dividends." They have found that its high efficiency saves fuel and eliminates smoke—that its high capacity saves investment in standby equipment—that its automatic cleaning and freedom from clinker troubles cut labor costs—that its simplicity lowers maintenance charges.

Repeat orders are the best evidence of stoker worth. The new bulletin gives the reasons for them. Write The Under-Feed Stoker Co. of Canada, Limited, 146 King St., Toronto, for your copy.

Users Testify to the Saving Power of Files Stokers

ONE user of Files Stokers says a single installation (3,600 H.P.) saved enough coal to pay for the stoker investment in five months.

The average rating for this period was 223%.

Another user has written to say "While we have not made an actual test we would judge the saving in coal to be 10% to 15% as our load increased 25%. We are now able to obtain required steam without difficulty, which we could not do with down-draft furnaces."

Quoting from the letter of a third user the fuel-saving merits of Files Stokers is attested as follows: "Our Files Hand Stokers have now been installed about two years, during which time they have paid for themselves twice over if we consider the saving in fuel."

Files Stokers Achieve Results because:

1. They give correct distribution and proper proportion of air according to load carried.
2. The fuel bed is at all times kept clean and uniform.

You will be interested in the details of design of the Files Stoker. Write for complete information.

Waterous

BRANTFORD, ONTARIO, CANADA

The Peck Carrier for Handling Both Coal and Ashes

ONE sturdy reliable unit, instead of several inferior machines for accomplishing the same results.

Handles both coal and ashes with less upkeep than required for individual machines for coal and ashes.

Costs practically the same as elevators, conveyors, skip hoists and other equipment required to do same work—and is more dependable.

Operation and maintenance is less than for any other types of coal and ashes handling apparatus.

Minimum power required, the equipment runs slowly, is noiseless, and is always ready for service.

Back of the Peck Carrier stands the reputation of this Company—with hundreds of successful installations. Full particulars in Catalog 220.

PACKING

There Is No Economy

in using a rod packing that does not meet the exacting conditions of present day engineering.

If the packing is not entirely heat resisting it will quickly char and fall apart—temperatures are high.

If the packing is made of heat resisting materials and does not contain sufficient lubricant it will quickly harden and become useless.

"Palmetto" meets the conditions, because it is absolutely heat resisting, and carries such quantities of lubricant that it does not harden.

If you do not know "Palmetto" let us send you working samples to test—no charge.

More Power for Prosperity

OF ALL the economies you can effect in your plant, the installation of modern, new, high grade Boilers will be the most far reaching. Boilers that leak steam, that leak heat, that require constant patching up and shutting down for repairs and have a regular "hog appetite" for coal are an intolerable expense, none the less dangerous because you probably don't see them often or hear much about them. Remember—the boiler is the heart of your power plant and every dollar wasted must come out of your profits. We make boilers of all types and sizes for either power or heating duties. Our 35 years of experience and our reputation for high class work at moderate prices are factors that warrant you corresponding with us at once on this important subject.

Big savings—

with the National Hand Fired Stoker

The special coking arch construction, possible only with the downward slope of our fire grates, is the most successful smoke consuming device you can use. Yet this arch is only one of several features that make the National Hand Fired Stoker a wonderful fuel and labor saver. The downward sloping banks of grates operated by convenient Pusher Rods from the front of the furnace enable even "green" help to get perfect stoking results with almost any grade of fuel.

The National can be installed with your present Boilers. Send for illustrated booklet.

Ingersoll-Rand Class PRE-2 Compressors at the International Nickel Co.'s Creighton Mine.

Ingersoll-Rand Compressors

The Choice of Men Who Know

The mining Industry being the largest and oldest users of Air Compressors and the most dependent upon them are probably better qualified to judge compressor values than any other class of user.

Therefore, those requiring Compressors for construction work, pumping, gasoline extraction or industrial purposes of any kind can best be guided by selecting the types adopted by experienced mine operators.

In every recognized mining camp on the globe, "Ingersoll-Rand" Compressors predominate. Many of them have also found their way on mule back, or by other primitive modes of transportation into the heart of Africa, the ice-bound regions of the Far North, or over the mountain passes of Mexico, Columbia, Peru, Chili and other remote parts of the world.

"Ingersoll-Rand" Compressors are there because they have proven their worth—from a cold dollar and cents stand point. Workmanship, materials and design are up to the minute—the product of an organization with over 50 years experience in this field and who knowing the conditions under which this class of equipment operates build accordingly.

"Ingersoll-Rand" Compressors are built for all classes of service and for all drives in a complete range of sizes, from 6 to 10,000 cubic feet per minute. Standard and special units for gasoline extraction, handling ammonia gas and for high pressure service as well as a complete line of straight-line and duplex dry vacuum pumps are also available.

Detailed information concerning any or all sizes and types of "Ingersoll-Rand" Compressors or Vacuum Pumps forwarded on request.

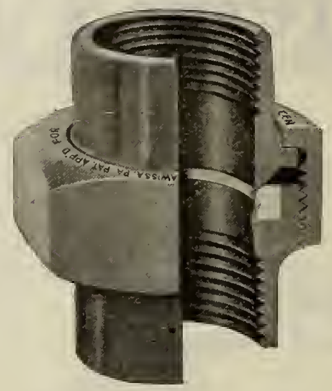
The "CATAWISSA" Forged Steel UNION



An Unusual Union

You lose no time tearing down lines on account of union troubles, when the "CATAWISSA" is on the job.

Forged from refined steel bars it has unusual strength and toughness and will stand any amount of abuse. Seats made from ordinary forged steel, brass or monel metal.

Monel Metal Seat

The toughness and durability of Monel Metal is a decided advantage when used as a seat for the "CATAWISSA." It makes it proof against the "wire-drawing" or cutting effect of the steam, is non-corrosive and is unaffected by small cutting particles that would otherwise cause leaks. It is especially suitable for high pressure temperature.

The high grade material used enables the "CATAWISSA" to withstand shock and vibration without the usual crystallization and breakage.

"CATAWISSA" Unions are thoroughly tested under water with compressed air—the best known method. You should investigate these "unusual" unions.

AMPLE RECESS FOR PIPE END CLEARANCE.

The Superior Steam Valve

The Mueller A-3006 Steam Valve has proven its superiority under high and super-heated steam pressures so that to-day repeat orders from customers satisfied with samples are the rule, rather than the exception.

If you have not acquainted yourself fully with this valve, there is no better time than right now. Made in a complete range of sizes, from 1/8" to 2". Send for sample and make your own test.

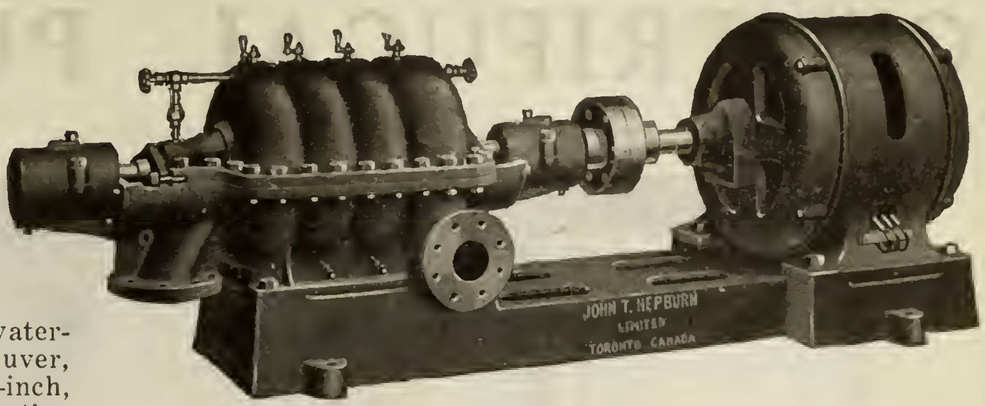
HEPBURN PUMPS

For Reliable Waterworks Service

In The City of Vancouver



In the Lynn Canyon waterworks, North Vancouver, there is installed a 3-inch, 4-stage pump, operating against a head of 600 feet. The pump is a HEPBURN and it was installed to safeguard the North Vancouver district water supply. The Hepburn pump was chosen for this important work because of its recognized dependability.

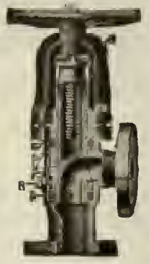
The Hepburn pumps are built on the most improved lines—Centrifugal, Simplex and Duplex. Write for complete information regarding Hepburn Pumps and Hepburn Hand and Electric Overhead Cranes, Vertical Engines, Castings and Forgings.

JOHN T. HEPBURN LIMITED

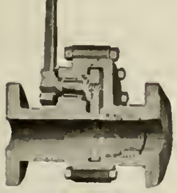
Engineers and Iron Founders **18-40 Van Horne St., Toronto**

The Yarway Tandem

Combination of slow-opening plunger type valve—the Yarway Seatless—and quick-opening swing-gate valve—the Yarway Double-Tightening. Complies with A.S.M.E. Code and Boiler laws of all States. Absolutely dependable for efficient blow-off service and long life.



Yarway Seatless Blow-Off Valve, (Formerly the Simplex).



Yarway Double-Tightening Valve.

Unconditionally Guaranteed For Two Years

The Yarway Tandem, consisting of the Yarway Seatless Blow-Off Valve and the Yarway Double-Tightening Valve, is unconditionally guaranteed for a period of two years from date of installation. Should any part of either valve fail within that time, it will be replaced or repaired without cost to the user.

Two years, however, by no means represent the maximum service that can be expected from the Yarway Tandem. We hear of Yarway Seatless Blow-Off Valves in service nine and ten years without repairs; and the first Yarway Double-Tightening Valves, installed several years ago, are on the job to-day.

The Yarway Tandem is fully described in Booklet B-410. May we send you a copy?

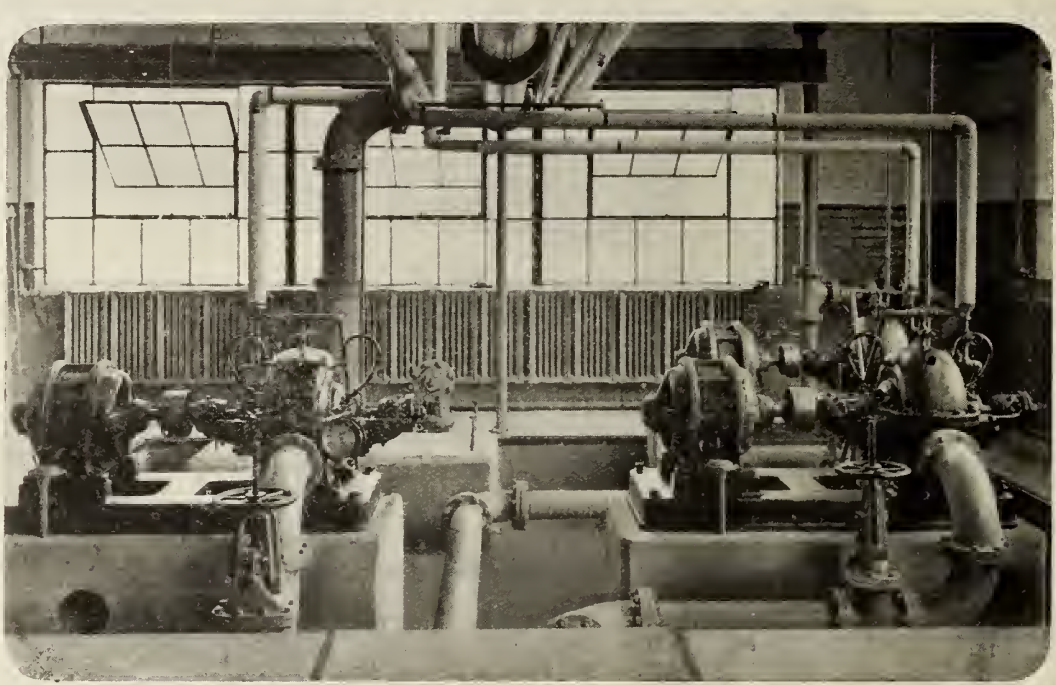
CENTRIFUGAL PUMPS



3-Rees RoTURBo Circulating Pumps at the Plant of The Match Co., Limited, Berthierville, Que.

Freedom From Wear

The low velocity of the water through all passages of REES RoTURBo Pumps results in almost complete freedom from wear, even when gritty water is being pumped. Furthermore, the prime mover is insured against over-loading by its self-regulating feature. REES RoTURBo Pumps give permanently efficient service over a wide range of duties. Their many features are minutely explained in the REES RoTURBo bulletin. Shall we send you a copy?

POWER HOUSE

ESTABLISHED 1907 *Toronto, July 5th, 1923* A SEMI-MONTHLY NEWSPAPER

C.A.S.E. Convention in Toronto Best Ever!

J. J. Sullivan, of Ottawa, Chosen President for Ensuing Year—Montreal to be Scene of Next Gathering—Spirit of Goodwill Dominates Engineers and Exhibitors Alike

THE thirty-fourth annual convention of the Canadian Association of Stationary Engineers was, judging from the attendance, and the spirit evinced at the various meetings, one of the most successful ever held. The official registration was nearly 500, and many more attended the banquet, the concerts, and the power equipment exhibition.

The banquet Monday night, June 25, in the Hotel Carls-Rite, Toronto, at which members of the Exhibitors' Association were the hosts, was the best attended in the history of the organization, and the entertainment was of an unusually high order.

Robert McLaren, chief engineer, Massey-Harris, Ltd., and president of Toronto No. 1, who has been a member of the association for the past eighteen years, in welcoming the guests, declared that 1923 so far had been the best year in C. A. S. E. history, and urged all members to spread abroad the spirit of goodwill which is the fundamental essential of success. Alderman W. H. Shaw in voicing a plea for "Education—the Foundation of Good Citizenship," stated that more mathematics and science should be added to the curriculum of the public schools of Ontario.

After Duncan Cowan had left the audience applauding his solo effort for more than a full minute, a toast to the Department of Education was proposed by Geo. F. Galloway of London, Ont., secretary of the Grand Lodge.

Defends Boiler Law

The unusual spectacle was then witnessed of a government official, J. H. H. Ballantyne, deputy minister of labor. defending the boiler inspection law of the province, as the term of office of his chief in the U. F. O. government was being terminated by the voters of Ontario. Mr. Ballantyne stated that "it was not desirable to change the present law, until it had had a fair trial," as the complaints he had received to date, he claimed, were few. He, however. admitted, that if the Act was unsatisfactory it should be rectified. adding that as at present there is a strong tendency toward the use of electrical energy, any changes should cover future electrical development.

J. M. Brown, chairman of the Board of Examiners, explained briefly the grading of engineers and the issuance of certificates. To show how difficult the requirements have become, he pointed out that 70 per cent. of the applicants failed to pass last year. There are eighty first-class certificates held in Ontario.

J. T. Burke, chief inspector of factories, also spoke, his remarks being followed by a song by Earl Hetherington, which was well received.

MISS ARLENE JACKSON,
Power House Entertainer.

Jack Armour, of Power, then put everyone in good humour with a flood of oratory.

Miss Jackson Triumphs

Miss Arlene Jackson, in her initial appearance before members of the C. A. S. E. by arrangement with Power House, was the outstanding feature of the entertainment.

A winsome miss, whose billing in "big time" vaudeville, "syncopated songs at the piano," aptly describes her act, contributed four numbers to the program. Her first, "The Old Swimmin' Hole," struck a popular note with its echoes of boyhood days. The second, a parody on Gallagher and Shean, was improvised around the labors of Arthur Murphy, editor of Power House. Her third number was a careful characterization of Bert Williams, the famous star, in his Broadway success "Somebody Else," and her final offering, "Down in Indiana" won the favor of everyone.

It is hardly logical to expect an audience to applaud heartily when individually and collectively it is wiping its brow with one hand and more or less vigorously fanning itself with the other, but this snappy and entertaining turn brought down the house. It was a real vaudeville "spot holder."

T. H. Fenner, former editor of Power House, was the next "act," on the bill, his song offering winning favor.

The election results were announced during the evening.

Grand Lodge Opens

On Tuesday, June 26, at 9.30 a.m., the official opening of the Grand Lodge took place in the Central Technical School Library, being followed at 10.30 by a general meeting of engineers and exhibitors.

W. S. Kirkland, assistant principal of the night technical school, in a speech on behalf of Dr. A. C. McKay, who was out of the city, welcomed the delegates and outlined the educational value and history of the school, emphasizing the fact that the institution had its origin in the efforts of pioneer members of the C. A. S. E.

Short speeches in reply were made by Earl Hetherington, G. C. Keith, Geo. F. Galloway and Geo. J. Soucy, chairman of the convention committee.

Mr. McLaren in a tribute to the interest and enthusiasm of the exhibitors and delegates, said in part: "There could have been no better place selected for the purpose of this convention and exhibition than the Central Technical school. and I am sure we all appreciate the kindly interest and patronage of Dr. A. C. McKay, director of technical education for the City of Toronto.

"It was he who made it possible for us to have such fine and convenient quarters. I wish personally to extend a most hearty welcome to all our guests and patrons. We trust that your visit here will be both a source of pleasure and profit and should you leave us before the exhibition is concluded, Remember it, Boost it, and tell others to come to it."

Mr. McLaren then emphasized the value of the publicity Power House had given the C. A. S. E. in the past year, exhibiting many pages dealing with C. A. S. E. activities to the delegates from the platform. In concluding, Mr. McLaren asked Campbell Bradshaw, managing editor of Power House to address the delegates.

Urges Co-operation

Mr. Bradshaw in urging co-operation and unity warned the delegates of the dangers of one-man control and petty jealousies in any organization. He pledged his individual efforts toward the expansion of the organization in the coming year.

Before adjournment Mr. Soucy again spoke, saying in part: "Not many years ago nearly all practical engineers refused to have anything to do with theorists or professors of engineering; however, to-day the attitude of nearly all engineers is completely reversed, because to-day nearly all theorists have a practical working knowledge of their subjects, with the result that they can meet the practical or stationary engineer on his own ground. To-day the operating or stationary engineer is seeking to acquire more and more of the theoretical and technical knowledge required to fit him for a higher grade of certificate or a better position. The graded license has contributed very largely to this result; however, there is no doubt that technical newspapers and schools have made possible in many cases the results obtained.

"As chairman of the educational committee of the C. A. S. E. I wish to say that we cannot, nor do we ever hope, to displace technical education, but rather to supplement it by affording a sort of exchange or clearing house for practical problems. Our aim and purpose can best be accomplished by the establishment of operating engineers' clubs in all large centres where the engineer who is off duty or out of employment can go and see a permanent exhibit of power plant equipment and supplies, and attend lectures or classes of instruction in practical operation. I believe such a scheme is not only possible, but that it is the only one which will ever succeed in holding engineers together and in the end prove the most economical and effective from the supply men's stand point."

Tour Technical School

Tuesday afternoon was devoted to a tour through the mechanical departments of the technical school, conducted by M. Barry Watson, director of the engineering department of the school.

A concert was held in the main auditorium in the evening, which consisted of movie films, both technical and comic, a radio concert, directed by M Watson, and an organ recital by Geo. H. Graham, M. A.

Wednesday opened with a meeting of the Grand Lodge in the technical school library. At 12.30 all engineers and exhibitors assembled at the front entrance of the school on Lippincott St., for the official photograph. The Grand Lodge held a further meeting at 1.30 p.m. which was followed by a second tour of the school, again under the supervision of Mr. Watson. The evening concert was similar to that of Tuesday evening.

Elect New Officers

Thursday was featured by a meeting of the grand lodge for the election of officers for the ensuing year. The following engineers were elected:

Immediate Past President—Geo. F. Galloway, London, Ont.

President—J. J. Sullivan, Ottawa, Ont.

Vice-President—Robt. McLaren, Toronto, Ont.

Treasurer—E. J. Groome, Kingston, Ont.

Secretary—Geo. J. Soucy, Toronto, Ont.

At 11.30 a.m. the exhibitors held their annual meeting, and the following officers were elected:

President—Howard Fletcher, of Garlock Packing Co.

Vice-President—H. A. Hatfield, of Babcock & Wilcox.

Treasurer—L. M. Archibald, of Dart Union Co.

Assistant-Secretary—Geo. L. Wilkinson.

A vote of thanks was tendered C. B. Turner, who has acted as chairman of the exhibit committee for some years.

As the next convention city, Montreal was unanimously chosen.

Exhibits in Three Rooms

The three rooms in the central technical school devoted to the exhibits of machinery, appliances, asbestos, compounds, etc., were a veritable bee-hive, and engineers as well as visitors received much valuable information. The booths were well laid out and demonstrators and exhibitors were on hand with the desired information.

G. F. Sterne, of G. F. Sterne & Sons, consulting chemical engineers of Brantford, Ont., displayed silicate of soda for use in the prevention and removal of boiler scale, also their Monolith for making one-piece refractory boiler fire box and industrial furnace linings.

The Dearborn scientific treatment of boiler feed waters sold by the Dearborn Chemical Co. Ltd., of Toronto, to elimin-

Delegates and Exhibitors at 34th Annual Convention of the Canadian Association of Stationary Engineers.

ate scale formation and corrosion in boilers, was ably discussed by the company's representatives, G. Wilson and W. W. Jamieson.

The Crane Packing Co. Ltd., of Chicago, represented by F. R. Yeomans, exhibited engine packing goods and boiler roof supplies, laying particular stress on the "John Crane" flexible metallic packing.

Keasby & Mattison, of Ambler, Pa., with a branch office in Toronto, manufacturers of asbestos products of every description, were represented by B. Peltz, who demonstrated their asbestos pipe covering and asbestos tubing.

Howard G. Fletcher, of the Garlock Packing Co., of Hamilton, went into the subject of asbestos in all its stages from rock to the finished product, as well as the various stages in the manufacture of rubber, laying particular stress on the Garlock engine packings.

Dart Union Exhibit

The Dart Union Co. Ltd., of Toronto, had a special exhibit of the Dart union fitted with bronze rings. This was kept in water during the entire convention to show that the rings remained free from rust and corrosion. The ball joint of the Dart union was shown by a large ball standing on a raised union. L. M. Archibald was in attendance.

Walter H. Reid, of the Argus Manufacturing Co., Toronto, discussed various materials for the water-proofing and air-proofing of surfaces, also the Argus caulk and Argus boiler coat as coal-saving devices.

The operation of the Babcock & Wilcox boiler with B. & W. chain grate stokers were ably explained by H. A. Hatfield of the Toronto office of the company.

C. B. Turner, of C. B. Turner & Co., of Toronto, demonstrated an automatic boiler cleaner and the Hercules expanding boiler tube.

Plibrico, a jointless furnace lining, Boico boiler compound, and shell-bar grates, greeted the visitor to the second room, and were in charge of W. D. Wilson of Shell-Bar, Boico Supply Limited, Toronto.

The Celite Products Company, of Montreal, had representatives from the Montreal and Buffalo offices, L. Russel and W. D. Van Arnam respectively. They demonstrated the Sil-O-Cel insulating brick for heat insulating work with the aid of a blow-torch.

Arrived Too Late

Unfortunately, the exhibit of the Bird-Archer Co., of New York and Montreal, did not arrive in time for the convention. P. B. Bird of this company was in town from New York, though the booth was in charge of H. C. Harrigan, sales manager of the Montreal office.

The exhibit of the Waterous Engine Works, Co. Ltd., of Brantford, was in charge of Wm. Welsh and Earl Buckley, who had on display one of their Files hard stokers.

The various workings of this exhibit caused much interest.

The only solder exhibit was made by the Magnolia Metal Co. Ltd. of Canada, Montreal. C H. Bechtel looked after everyone interested.

H. H. Gee, of Jenkins Bros. Ltd., Montreal, was particularly anxious that visitors should learn everything about the Jenkins valve and Beaver non-return valve. He had one of the largest displays, and also explained an air reducing valve capable of standing 200 lbs. pressure.

A new company just incorporated in Toronto, The Reliable Washerless Valves, Ltd., displayed the McIsaac valve which they are manufacturing. A. H. McIsaac, of this company, and inventor of the valve, was in attendance.

Darling Bros. Ltd., 120 Prince St., Montreal, represented by S. A. Jennings and D. Eggett, the latter of London, Ont., exhibited the Dexter valve reseating machines and Webster steam appliances.

Fire brick and Bours refractory furnace cement were explained by N. B. Jackes, of the Toronto Pottery Co. Ltd. The cement is a dry preparation and is claimed to resist flame.

The Jas. Morrison Brass Manufacturing Co., Toronto, Ont., had a large display in charge of A. Betton. Their chief exhibits were engine room set gauges and locomotive injectors. Beaver globe, angle and cross non-return stop and equalizing valves were all in paramount positions.

All Canada Product

A special feature in the Bull Dog lacing pointed out by E. Gordon of the Bull Dog Lacer Co. of Canada, Hamilton, is the fact that the wire used in it is entirely a Canadian product. It is a machine closed wire lacing that takes a staggered hold on the belt, by using a long and short hook alternately.

Thos. H. Fenner, A. M. E. I. C., former editor of Power House, is instructor in special courses for stationary engineers at the Shaw Correspondence Schools. He outlined courses to prepare for first, second and third-class examinations.

One of the largest exhibits was a Copes boiler feed regulator in charge of E. Dean Wilkes, of the Allen General supplies, Limited, sales engineers of Toronto. This machine was in operation fifty per cent. of the time, and had many interested observers.

A. W. Cash & Co., of Toronto, represented by W. T. Brickenden, displayed their damper regulator and reducing and regulating valves. An added feature of this booth was a lady's handsome hand bag, and a gentleman's set of Wahl pen and pencil. Visitors were given tickets,

Photographed for Power House at Toronto Central Technical School, June 27.

and on Wednesday evening they were drawn for, being won by Miss Holmes, 630 Lonsdale Ave., Toronto, and H. Marshall, engineer of Bingham's Limited, 84 Yonge St., Toronto.

W. W. Shears, of C. A. Dunham & Co. Ltd., Toronto, demonstrated the Dunham expanded outlet reducing valve and reducing pressure valve, also high pressure bucket traps and Dunham radiator traps.

Discussed Lubrication

W. W. Horsey, of the Imperial Oil, Limited, discussed oil and various lubricants for use in machinery and power plants. Pictures of their various refineries interested visitors.

W. Russell Sexton, of the W. R. Sexton Boiler Setting Co., Toronto, explained Sexton's Nonpareil shaking and dumping grate bars. He also gave information of fire-brick work and the retubing of boilers.

The Zeolite process, for the softening of water, used chiefly in laundries, hospitals, steam power plants, and textile mills, was thoroughly discussed by Robt. S. Hambleton, of the Refinite Co. of Canada, Toronto.

Wm. McKay ably represented the Goldie & McCulloch Co. Ltd., of Galt, manufacturers of boilers, pumps and engines.

Geo. Farrow & Son had an interesting exhibit explaining the coal wasted when boiler tubes become incrusted with scale.

Crane's Limited had a prominent booth at which the many types of valves this firm manufactures were explained.

Power House was also in evidence, the booth being under the direction of Miss M. Riopel and Walter Hudson.

Power was represented by Mr. Armour.

Other Booths Noticed

Ernie Wilkinson looked after the interests of the Lunkenheimer Company, and other booths noticed were Ontario Lime Co. Ltd., of Toronto, F. J. Downes, 23 River St., Toronto, manufacturers of feed water treatment, and dealers in Cole tilting return traps, and Canadian International Filter Co. Ltd., specializing in appliances for water softening and filtration plants; Quaker City Rubber Co., and Refinite Company of Canada.

The exhibition was open every day and evening during the convention.

Thursday, the last of the convention, which was to close with a picnic for exhibitors, engineers and their families and friends, dawned with rather a threatening appearance, and worst fears were realized, for about 10 a.m. it commenced to rain, and until evening kept up a fairly steady downpour.

Nothing daunted, however, it was decided to hold the picnic at the Horticulturad building at the Exhibition grounds, and to this meeting place those with cars very kindly conveyed those without, and by 3.30 p.m. everyone was on hand and the sports and races scheduled were in full swing. About two hundred were present, and practically all took active part in the proceedings.

There seemed to be a great deal of competition between engineers and exhibitors, but it is to their credit that they broke even in nearly every case. In the one hundred yard dash there was nearly a bad accident, when, having worked up steam to such an extent that he could not get under control, the "first in" had to spring right over the supper table, and all that was thereon. We are glad to say he cleared the top! The one foot hop race, also competed for by engineers and exhibitors, went to the engineers.

The ladies' candle race and the clothes pin race called for some patience, which was not at first realized by the participants, but all put up a good attempt to get to goal first. The potato race for engineers' wives and daughters only proved the "survival of the fittest," and it is quite safe to say that they never worked harder for a few ordinary "spuds."

Man's dominion over nature comes through the utilization of power. Upon this our present civilization rests. Therefore the generation of power is our most fundamental industry in Canada, and energy our most essential commodity. To-day we face a rapidly growing demand for power, a diminution of its sources of supply and increasing expenses of generation and distribution. In this situation the engineer must seek for vastly improved means of power production and more effective and economical means of distribution.

The kiddies had their races, and that none of them tumbled is certainly a credit to their sturdy little limbs, for, with so many, all excited, accidentally bumping and hitting each other with energetic arms, it seemed a miracle. All were happy, and as children will be, excited at the realization of days of anticipation, and perhaps it helped in making the day nicer for them, when each and everyone of them was presented with candy in some shape or form.

W. R. Sexton and J. Thompson, exhibitors, were among the most prominent in arranging the children for all their races, and for the general order which prevailed while all ages and sizes took their places and made ready for all the other tests of prowess. Geo. J. Soucy attended to the distribution of prizes.

Hungry for Supper

Supper was served, and it was a hungry crowd that sat themselves around the tables for the good supper that had been arranged by various members of the C. A. S. E.

The following were the lucky winners in the different contests:

1. One hundred yard dash, engineers and exhibitors—First, J. Fossey, large Union Jack; second, J. Thompson, Canadian flag; six consolations, small Union Jacks.

2. Balloon race, engineers' wives—First, Mrs. E. Bruce, pillow cover; second, Mrs. B. Scott, pillow cover; two consolations, handkerchiefs.

3. One foot hop race, engineers and exhibitors—First, J. W. Fossey, tape line, 100 ft.; second, B. Burgess, tape line, 75 ft.; first consolation, nickel-plated tape line, 3 ft.; second consolation, rule, 2 ft.; third consolation, rule, 1 ft.

4. Ladies' candle race—First, Gladys Bly, 1 pr. candle sticks; second, Mrs. J. B. Scharfe, 1 candle stick; consolations, candles and handkerchiefs.

5. Backward running race, engineers only—First, B. Burgess, two-year subscription to Power House; second, F. G. Galloway, one-year subscription to Power House.

6. Ladies' clothes pin race—First, Muriel Harvey, patent clothes reel; second, H. W. Vallis, patent clothes reel; consolations, handkerchiefs.

7. Men's smoking race, 75 yards and return, engineers only—First G. F. Galloway, pipe; second, I. V. Huber, pipe; consolations, corncob pipes.

8. Potato race, engineers' wives and daughters only—First, Hazel Scharfe, patent peeler; second, Mrs. J. Miller, patent peeler; six consolations, peelers.

9. Wheelbarrow race, team to consist of engineer and exhibitor—First, J. Thompson and H. Marshall, pipes.

10-a. Little boys' race—First, Albert Potter; second, E. H. Perkins.

10-b. Little boys' race—First, Geo. Harvey; second, Frank Miller.

11-a. Little girls' race—First, Nora Faulkes; second, Hazel Scharfe.

11-b. Little girls' race—First, Violet Harvey; second, Flo Harvey.

There had been only one race billed for the boys and girls, but it was found that there were so many they divided them up according to size, the larger ones in each party running together, thereby giving the smaller tots a better chance. Owing to weather conditions, the softball game scheduled between engineers and exhibitors to take place in the evening had to be cancelled.

Trade Catalogs

The Combustion Engineering Corporation Ltd., Bank of Hamilton Building, Toronto, have published a 32-page treatise on the subject of oil burning, outlining the advantages of the Quinn Fuel Oil Burning Equipment and emphasizing the absurdity of rumors circulated from time to time to the effect that the oil supply of the world is nearing exhaustion. The equipment described in the book is designed specifically for the purpose of getting the greatest number of heat units out of the oil it burns and is installed to-day, it is claimed, in numerous plants where the decision to buy is based upon the everyday operating results assured by the equipment selected.

The book is ready for distribution to any Canadian engineer who cares to write for it.

The Value of Slide Rule in the Power House

By ARTHUR MURPHY*

A Brief Outline of the Principles Involved, Showing Simple Methods of Calculating—Easy Ways to Read the Scale and Illustrations of Its Value to the Engineer

THE slide rule is one of the most useful pieces of apparatus that can be used around the modern power plant. Unfortunately, in the past it has been used almost solely by designing engineers to make calculations without waste of time or energy. Operating engineers and non-technical men have come to regard it as being too complicated for their use, disregarding the fact that if they would take certain mathematical laws, which they do not need to understand, for granted, and spend about fifteen minutes a day practising with the rule, in a very short time they would be able to solve any ordinary mathematical problem of the power house.

Once a person has learned the use of the slide rule, he will find it such a saving in time that he will wonder why he did not learn all about it years ago.

Though the principles governing the operation of the slide rule may be learned in a few minutes, it requires patience and practice before the engineer can become an expert in its use. It is unwise to spend several hours in striving to master the intricacies of the rule, as such concentration results in fatigue and the mind becomes so confused that more harm than good is done. Whenever an engineer has a few minutes to spare, however, he should pick up the rule and practise with it.

It will be found helpful to work out simple multiplication with the rule, later checking the result by longhand, in this way one can soon find how close it is possible to work with the rule as well as find out where and when care must be taken in the setting.

Market Many Styles

There are many styles of slide rules on the market from the simple type designed for the merchant to the log for the mathematical gymnast. Though special rules are made for special work such as the Allan Friction head slide rule for piping and hydraulic problems, the power computing slide rule for steam, gas and oil engines; the chemist's rule, and others, the Mannheim or polyphase slide rule for general work will be found to be most suitable, containing a sufficient number of scales for the power house.

A good slide rule can be obtained at reasonable cost but if the beginner so desires he can purchase for a small amount a plain boxwood or bamboo rule.

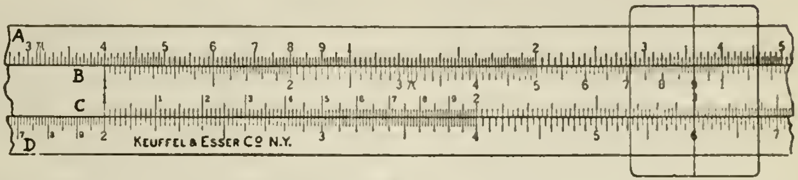

Fig. 1.

Suppose we take two yard sticks and place them side by side with the zero of one corresponding in line with the 14 inch graduation of the other; now if we look under the 20 inch mark on the first we find the mark on the second is 34. In other words by adding spaces that represent a number of units, we accomplish the same result as if we added the numbers.

Ability to use a slide rule and knowledge of its application to the power house has been a subject of much inquiry in Canada in the past month or two. This article, which shows how to read the scales, will be followed in the July 20 issue by typical problems of the engineer and their solution by the use of the rule. The electros were made by the Keuffel & Esser Co. to illustrate the value of the rule to the engineer.

The distance on the yard stick between 1 and 2, 4 and 5, 9 and 1 is the same, or in other words, the yard stick is a scale of equal parts.

The Use of Logarithms

It is not the intention of this article to explain the use of logarithms and how they are obtained. If the logarithm of a number is obtained and to that be added the logarithm of any other number, the sum obtained will be the logarithm of the product of the two numbers.

In a similar manner the subtraction of the logarithm of one of the numbers from the logarithm of the other gives the difference as the quotient of the two numbers.

Thus by the addition of the logarithm of numbers we accomplish the same as by the multiplication of the numbers.

If on our sticks we mark off the spaces to represent the logarithms of the numbers from 1 to 10 and place the two scales together, we have in effect the simple slide rule.

In adding the spaces on the slide rule we in effect multiply the numbers indicated on the scale on the rule.

Suppose we start with the simple slide rule containing only scales A, B, C, and D on its face as in Fig. 1. The two bottom scales C and D will be found very convenient for multiplication and division, consisting of 9 major divisions of unequal length, designated by the numbers 1, 2, 3, 4, 5, 6, 7, 8, 9 and 1, reading from left to right. The numbers at the extreme right and left are called the right index and the left index respectively. The space 1—2 is the longest in the rule, gradually decreasing in length to the shorter space 9—10. Each of the nine major divisions are divided into 10 minor divisions but it will be noticed that the major division 1—2 is divided into 10 minor divisions all of which are numbered. In no other major division are any sub-divisions numbered. All the minor divisions in the major space 1—2 are sub-divided into 10 unnumbered spaces.

Divided Into Five Parts

In the other major divisions 2—3 to 9—1 each sub-division is unnumbered and is only divided into five parts, which are not numbered.

Each minor division in the major divisions 2—3 and 3—4 is divided into five parts, in the major divisions 4—5 to 9—1 each minor division is divided into two parts only.

The left hand index 1 was arbitrarily designated as 100 then the other divisions assigned numbers to correspond.

It must not be forgotten that a number such as 4 in the major division may

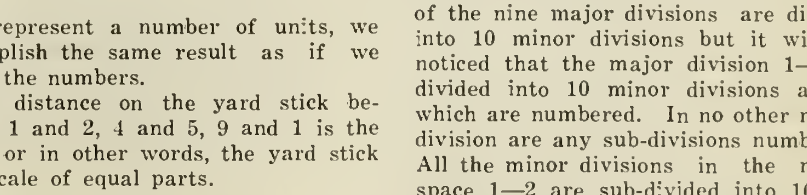

Fig. 2.

---

*Editor, Power House.

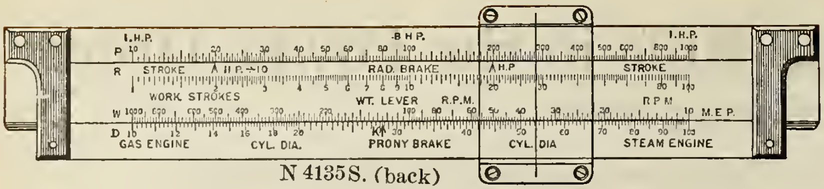

Fig. 3.

represent .0004, .04 or 4,000 or any other simple multiple of ten, depending on the placing of the decimal point. If the value of 3 in the major division is 300 then in the minor division 1—2 the value of the smallest division is 1. In the 2—3 or 3—4 each small division has a value of 2. In the major division 4—5 and all the remaining divisions a value of 5.

From the foregoing it would appear difficult to read the scale; a little practice, however, will do more good than a page of instructions.

Read Scales Quickly

Before any calculations can be made on the slide rule one must be able to read the scales quickly and accurately. In referring to Fig. 9, C and D scales, assuming that the left hand index has a value of 100, the value of each space is indicated by the numbers opposite. In the actual slide rule the numbers 101 and 102, etc., are omitted, the numbers representing 110, 120, 130, etc., only being marked.

This is on account of the fact that the figures would be so small as to be scarcely discernible, and their presence would only lead to confusion.

In reading a number always take the first figure to the left of the prime line, the second figure of the number on the secondary line to the right, then the third figure on the subdivision, thus 315 read three—one—five, not three hundred and fifteen.

Study carefully the numbering in Fig. 9 and when in doubt as to the correct reading in working problems, consult it.

The first figure of a number locates the major division. Under no circumstances are any numbers whose first figures commence with 1 found in any but the major division 1—2; similarly the numbers that represent any graduation in the major division 1—2 must always begin with 1. This may appear simple but more mistakes are made by beginners not realizing this, than by any other cause. The major division gives the first figure of the number and similarly the first figure fixes the major division.

Minor Division Fixed

Having located the major division of the number, the minor division is fixed by the second figure from the left of the number.

Thus 345, 380 and 310 are all in the third major division; in 324, 126 and 925 the graduation representing these numbers is found in the third minor division of their respective major divisions, similarly in 106, 203 and 709, these numbers are located in the first minor division of their major divisions.

The location of the third figure in each number is equally as easy if the line happens to fall on a graduation but presents a little trouble if it comes between the lines, so will be discussed later when the reader has grasped the fundamentals.

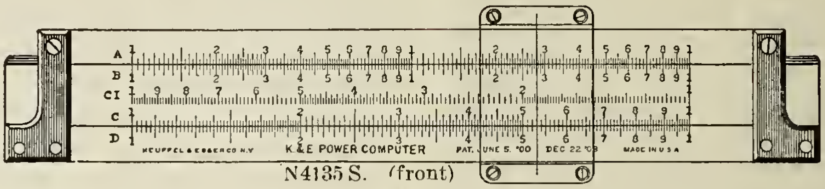

Fig. 5.

Try reading the graduations on the two lower scales in Fig. 7.

On the C scale the number in the major division nearest to the left of the hair line is 6, it may be 6, 600 or 6,000, the fixing of the decimal is performed later.

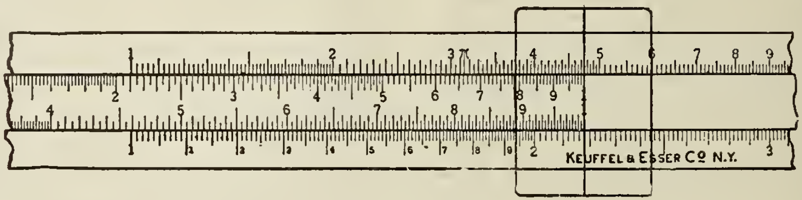

Fig. 6.

The hair line falls on the 2 graduation mark in the 6—7 major division. The number then must start with 62. Referring to the lower or the D scale, the hair line is in the first major division 1—2, the first figure on the left of the number must be 1, the figure to the left of the hair line in the minor division is 3 and the hair line being half way between 3 and 4, the number must be 135.

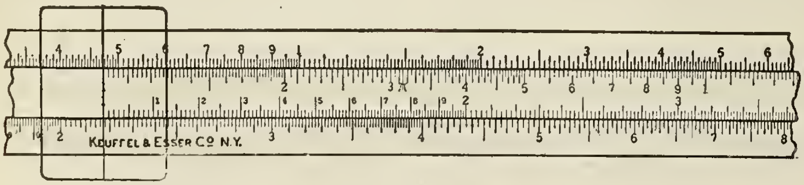

Fig. 4.

Try reading other numbers such as 230, 420 and 236.

Doubt Its Accuracy

Persons who are none too familiar with the slide rule will frequently state that it is not accurate enough for their work. With ordinary precautions and a little care in setting the scales and in reading the graduations, it will in many cases be found to be as accurate as necessary for ordinary engineering problems, certainly in some cases quite as close as the observed readings of pressure gauges or of thermometers.

With the 10 inch slide rule three significant figures can be read, the fourth is doubtful. In reading at the left of the rule four figures can be read, as in the number 1235, the 123 are certain, the 5 might be 4 or 6, giving an error less than 1 in 1,000, or correct to one tenth of one per cent.

In general it may be said that readings closer than 1 per cent. may be secured on any portion of the rule and in many cases at the left of the rule to one tenth of one per cent.

Simple Calculations

Multiplication:—Find the value of 2 × 3, see Fig. 1.

Opposite 2 on scale D set 1 on scale C. Then move the indicator or glass runner so that the hair line is over 3 on scale C. Directly below this you will find 6, the answer.

Division:—Suppose we wish to divide 6 by 3. See Fig. 1. Opposite 6 on scale D set 3 on scale C. Then move the indicator to 1 on scale C. On D will be found 2, the answer.

Combined multiplication and division:

Example:—

$$\frac{1.35 \times 3.16}{6.2}$$

See Fig. 7.

Opposite 1.35 on D set 6.2 on C. If we try to move the indicator to 316 on C, it is impossible because 316 lies beyond the extremity of D. In such a case proceed as follows:—

Move the indicator to the right hand index of C. See Fig. 6.

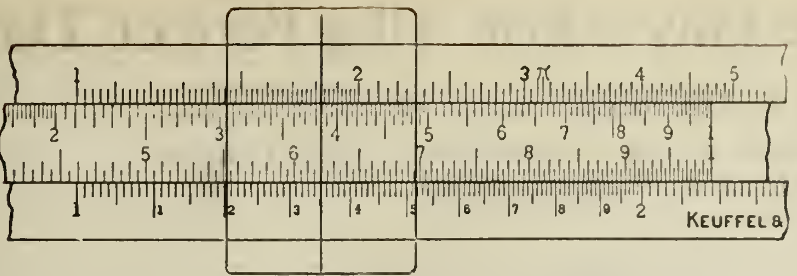

Fig. 7.

Then move the slide, setting the left hand index of C to the indicator. See Fig. 4.

Now we can move the indicator to 316 on C. See Fig. 2, and under 316 on C read the answer 688 on D.

A rough calculation for the decimal point gives us 1 × 3 ÷ 6 or 3 ÷ 6 = .5 and stretching our imagination so that .5 looks like .688 we have .688.

Squares and square roots:—To square a number means to multiply by itself, that is, $3^2 = 3 \times 3 = 9$. On the slide rule this is done as follows:—

Referring to Fig. 8, set the indicator to 3 on scale D. Above on scale A, using the face of the rule under the indicator we find 9 the answer.

In the same manner in Fig. 8 find the square of 2. Finding the square root is just the reverse. To find the square root of 9 we find the number which multiplied by itself will give 9; the square root of 9 is indicated thus $\sqrt{9}$.

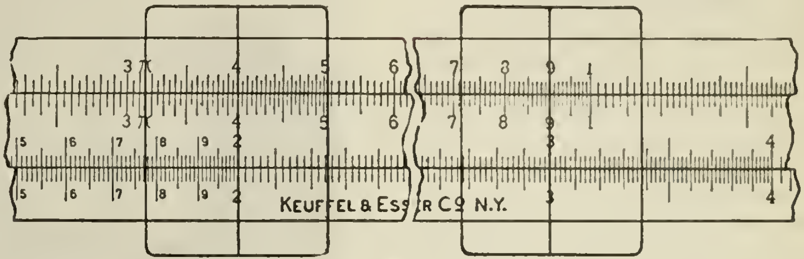

Fig. 8.

More care is required to find square roots than in finding squares.

Set the indicator to 9 on scale A being careful to use 9 on the left hand half of the scale; the 9 on the right hand is really 90. Below 9 on scale A read the answer 3 on scale D.

Find in Fig. 8 the square root of 2.

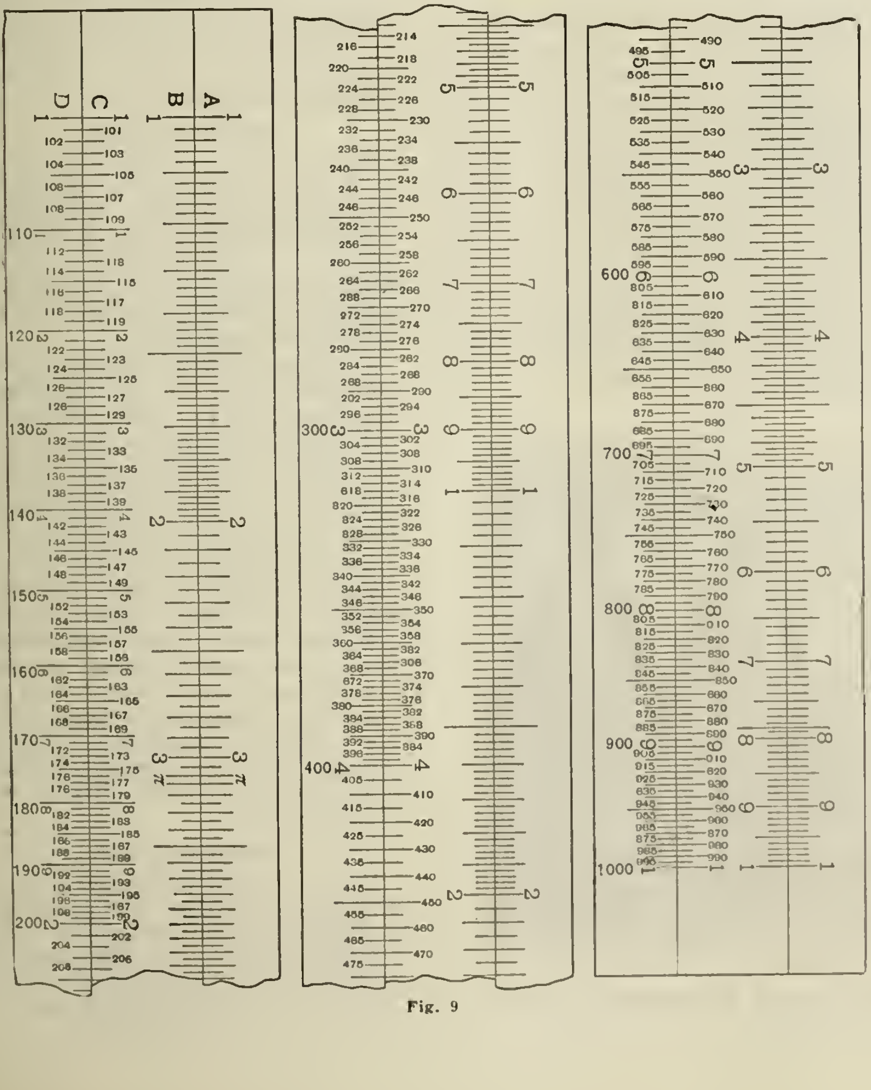

Fig. 9

Oliver Machinery Co., Grand Rapids, Mich., manufacturers of machine tools and woodworking machinery, who specialize on pattern maker's machinery of every description, have entered into an arrangement with the Canadian Fairbanks-Morse Co., Montreal and Toronto, to represent them exclusively in the sale of their machinery in Canada, thus giving their Canadian customers the advantage of buying without the annoyance of entering through the customs.

Power Notes

H. C. Harragan, McGill Building, Montreal, has been appointed Canadian representative for the Bird Archer Chemical Co.

C. B. Smith, chief engineer of the Union Bank of Canada Building, corner King and Bay Sts., Toronto, has resigned his post after 14 years service.

Ernest Norgate, formerly of the Coleman Lamp Co., has been appointed chief engineer of the Union Bank of Canada Building, Toronto.

The Canadian Electrical Association elected the following officers at their annual meeting held in Montreal: President, P. R. Davies; vice-presidents, R. J. Beaumont, W. P. Axton Little, and J. B. Goodyatt. Executive committee: A. P. Dodridge, M. A. Pooler, J. E. Tanguay, N. S. Baden, W. A. Bucke, A. B. Cooper, A. A. Dion, and A. Munro Grier, K. C.

The Mohawk Electrical Co., Brantford, Ont., have been granted the contract for the electrical work in the new addition to the Brantford Collegate Institute.

Sealed tenders will be received by C. J. Brown, chairman, Committee on Public Utilities, City Clerk's Office, Winnipeg, Man., up to July 23, 1923, for the manufacture of three Integral Type Super Heaters complete delivered to the site of the Steam Stand-by Plant, Winnipeg. Specifications may be obtained at the office of the City of Winnipeg Hydro-Electric System.

U.C.C. of E. Picnic Gay—For All a Perfect Day!

Queen City Council No. 27 Stages Annual Frolic at Ward's Island, June 23—Bumper Crowd in Attendance, Sports Program Enjoyed by Young and Old

IT IS EVIDENT that when the ladies of Queen City Council No. 27, Universal Craftsmen Council of Engineers, undertake to do anything, it is done thoroughly and goes over with a bang! This at least, is the opinion of those who attended the picnic at Ward's Island on Saturday, June 23.

The afternoon was ideal, and Old Sol in all his glory was a welcome guest. Engineers of the U. C. C. of E. with their wives and kiddies began to arrive by the 2 p.m. boat, and by 4 p.m. practically 200 were in attendance, and the contests scheduled began.

It seemed as though the different participants in the various races had been in training for some time, or else they are naturally very agile, for there was no cause for anyone to be ashamed of the place they reached at the finishing line.

Officers Queen City Council No. 27, U.C.C. of E. Left to Right—Mrs. C. L. Holmes, Mrs. John Grimshaw, Mrs. Fred Lewis, Mrs. L. Westwood, Mrs. T. C. McAree, Mrs. A. M. Auchterlonie, Mrs. J. L. Cuthbird, Mrs. William Bruce, Mrs. A H Stannah

All Races Enjoyed

All the races were thoroughly enjoyed by the contestants and audience. Beside the usual running races for all ages, there were a few contests of a rather novel type, for instance the ladies' balloon race, wherein the winner was the one who could blow a balloon to the bursting point in the shortest time.

The men's measuring race afforded amusement too, and it would be interesting to know how many of the men measured their shoes on their return home! The ladies' nail driving contest was a winner, and almost every lady had a "shot" at it, but all agreed that anyone who could drive a spike into the wood in four efforts, certainly deserved first prize.

And the kiddies! You certainly should have seen them! A picnic may be enjoyed by grown-ups, but the ones who really make it "go" are the children. After hearing about it for so long,, there is no doubt that realization brought more happiness to their little hearts than the anticipation. When a little boy in blue and white who couldn't possibly have been more than six years of age can say "Gee, I'm havin' even a better time than I thought I would," you know there was no drag to the party. And the supper—well, when it comes to that I don't know just where to begin. No wonder engineers are such strong, able looking men, for when their wives can place such delectable viands before them, they have absolutely no choice but to consume to capacity——no mortal man could withstand the temptation!

Six Past Worthy Chiefs, Canada Council No. 27, U.C.C. of E. Left to Right—T. C. McAree, W. Wolfenden, J. L. Cudbird, H. E. Terry, W. J. Hudson, and H. Potter.

Rain Ended Game

One thing that one and all regret is the fact that owing to a shower just after supper which later turned into a good sized electrical storm, the ball game had to be struck off the sports list. However, the interval gave people an opportunity to tell one another how they had enjoyed themselves.

A special feature, which was carried out regardless of the sprinkling, was a three-legged race, termed during this afternoon as the "Sexton Race," as Mr. and Mrs. W. Russell Sexton were responsible for it and presented the prizes. Power House was responsible for a Spoon and Egg Race for the ladies, and an obstacle race for the men. The ladies should certainly be congratulated on handling an awkward situation gracefully, for it takes no small effort to balance an egg on a tea spoon and guide yourself and it around a good sized tree! The men in the party certainly showed what stuff they were made of, in the obstacle race, for though shackled it was evident they were determined to reach the goal.

End Perfect Day

Everyone voted it a perfect day, and while of course, the storm caused a bit of disappointment, the spirits of the crowd were not visibly dampened. Particular mention must be made of J. L. Cudbird, A. M. Auchterlonie and G. H.

Jenkins, and their attention to business during the sporting events. Thanks and congratulations are most certainly in order to the Ladies' Picnic Committee, the following being members:—Mrs. W. Russell Sexton, Mrs. Darbyshire, Mrs. S. A. Longmore, Mrs. L. J. Cudbird, Mrs. C. L. Holmes, Mrs. A. M. Auchterlonie and Mrs. Albert Stannah.

The following is a list of races and winners:—

1.—Tot's Race.
Muriel Davis, Naomi Stannah, Trevor Cudbird, Elwyn Cudbird, Erma Morse and Aubrey Potter. Prizes, ball to each.
2.—Girl's Race, 8—12 yrs.
1: Elsie Jenkins, box of paints.
2: Doris Jenkins, string of beads.
3: Evelyn Norgate, handkerchiefs.
3.—Boy's Race, 8—12 yrs.
1: Albert Stannah, baseball.
2: Clarence Hunter, bat.
3: George Burridge, set of tools.
4.—Girl's Race, 12—15 yrs.
1: Agnes Stevens, Sol-rite pencil.
2: Gladys Wilson, manicure set.
5.—Boy's Race 12—15 yrs.
1: Alex. Auchterlonie, tie.
2: Wilber Hunter, pen-knife.
6.—Single Ladies' Race.
1: Violet Woodiman, lunch set.
2: Helen Westwood, ivory bud vase.
7.—Single Men's Race.
1: J. Auchterlonie, handkerchiefs.
2: Thomas Smith, tie.
8.—Married Ladies' Race.
1: Mrs. A. M. Auchterlonie ½ doz. sherbert glasses.
2: Mrs. Albert Stannah, aluminum collander.
9.—Married Men's Race.
1: Mr. A. M. Auchterlonie, two pairs socks.
2: Mr. L. J. Cudbird, handerchiefs.
10.—Ladies' Blowing Balloons.
1: Mrs. J. Miller, pr. embroidered pillow cases.
2: Mrs. J. Stephen, cup and saucer.
11.—Men's Measuring Race.
1: Mr. J. O'Brien, thermos bottle.
2: Mr. W. Russell Sexton, handkerchiefs.
12.—Queen City Officers. (Past and Present.)
1: Mrs. H. E. Potter, ½ doz. sherbert glasses.
2: Mrs. A. Baker, cup and saucer.
13.—Ladies' Nail Driving Contest.
1: Mrs. Fred Lewis, Royal Doulton plate.
2: Mrs. W. Russell Sexton, cut-glass butter tub.
14.—Ladies' Egg and Spoon Race.
1: Miss V. Woodiman, pr. silk hose.
2: Mrs. J. Miller, box of bon-bons.
15.—Men's Obstacle Race.
1: Mr. G. H. Jenkins, box cigars.
2: Mr. L. Westwood, speed indicator.
16.—Married Couples 3-legged Race.
1: Mr. & Mrs. A. M. Auchterlonie, electric iron.

Build 1,200 lb. Pressure Boiler

Babcock & Wilcox Co. See Early Solution of Water Level Indicator Difficulties

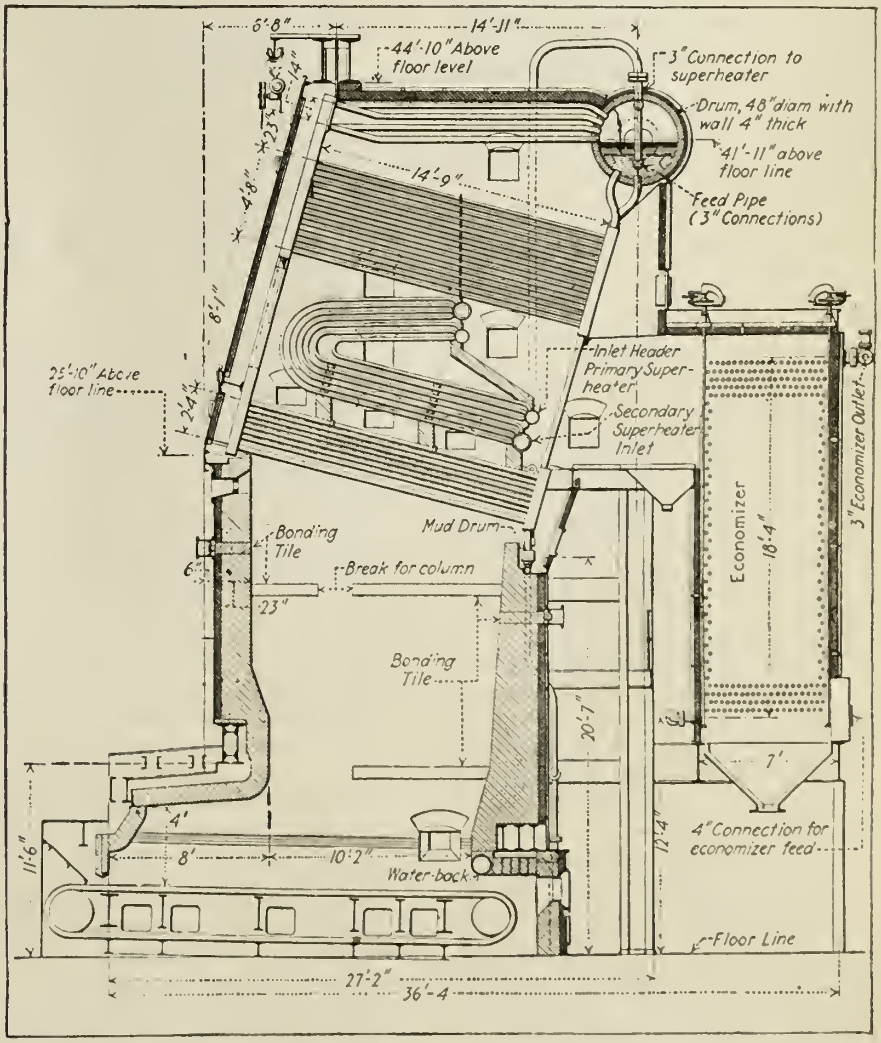
A. G. PRATT, vice-president of the Babcock & Wilcox Co., manufacturers of water tube steam boilers, in a letter to Power House this week, reported satisfactory progress in the experiments with water level indicators his company has been making for the last three months, in connection with a boiler being built in one of their shops, designed for an operating pressure of 1,200 lb. per sq. in. for use at the Calumet station of the Commonwealth Edison Company.

It is proposed to put in with this boiler a small "extra-high-pressure" turbine taking steam from the boiler at 1,200 lb. pressure and exhausting at 300 lb. pressure into the steam mains which supply the large turbines at the station.

In discussing super-pressure boilers of the future, H. A. Hatfield, when seen at the Toronto office of Babcock & Wilcox Limited, in the Bank of Hamilton Building, declared little trouble would be experienced by his company in constructing such boilers, the only difficulty being found in obtaining fittings which would stand up under the pressure contemplated.

New Setting Height

The unit at present under construction in New York is of the inclined-header, cross-drum type, and comprises a lower deck of eight-high sections of 2-in. tubes having a setting height of 25 feet. 9¾ ins., a primary and a secondary superheater in an interdeck space 8 ft. 1¼ in. between decks, an upper deck of seventeen-high sections of 2-in. tubes, horizontal 3¼-in. circulating tubes entering a 48-in. cross-drum, and a steel contraflow economizer. The lower deck is not baffled; the upper deck has a vertical baffle, causing the gases to make two passes. The complete unit is about 28 ft. wide, 36½ ft. deep, including the economizer, and 45



SECTION THROUGH BOILER, SHOWING SECONDARY SUPERHEATER AND FOUR-INCH THICK DRUM ft. high above the floor. The heating surfaces have not yet been definitely fixed, but they will be approximately as follows: Boiler, 15,750 sq. ft.; primary superheater, 2,120 sq. ft.; secondary superheater, 3,300 sq. ft.; economizer, 9,230 sq. ft.

The headers have 1¼-in. thickness front and back and ⅝-in. sides and are designed to give the tubes a stagger of nearly 4 in. The eight tubes in each section of the lower deck are expanded into nine-high headers, the tube space not filled being that next to the bottom. The mud drum is 7¼ in. square, 1 in. thick and extends through each side of the setting, with a flange for blow-off valves at each end.

The cross-drum is a forged steel cylinder 48 in. in diameter and 4 in. thick, with integral drum heads, each with a manhole closed by a 12 x 16-in. manhole fitting.

Unusual Arrangement

In order that the holes for connecting the circulating tubes to the drum may leave the largest practicable ligaments between circumferential rows of holes, an unusual arrangement of connections has been adopted. At the top of each uptake header two horizontal circulators are connected but the circulators from each alternate header are bent downward and sidewise so that they are connected to the drum in the same circumferential row as the circulators without such bends. This makes the distance between these circumferential rows about 16 in.

In the same way, the downtake nipples are not straight, but bent so that two downtake headers are connected to each of these circumferential rows. The drum has four 3-in. nozzles for safety valves, a 3-in. nozzle for the saturated-steam connection to the primary superheater, and two 3-in. feedwater connections.

The primary superheater has 8-in. headers drilled for three staggered rows of tube holes, with 72 tubes in each row. It is designed to raise the temperature of the steam under 1,200 lb. pressure to 750 deg. The secondary superheater has 11¾-in. headers drilled for four staggered rows of 72 tubes each. This secondary superheater incloses the primary superheater and is intended to raise the temperature of the exhaust from the extra-high-pressure turbine to 750 degrees.

The economizer has 44 rows of tubes with twenty 2-in. tubes 20 ft. long in each row.

In a parallel-connected armature there are as many paths through the windings as there are poles, which requires a set of brushes (positive and negative) for each pair of poles. In the series-connected winding there are only two paths through the armature, irrespective of the number of poles; hence only one set of brushes is necessary, although in large machines more brushes are usually fitted.

Industrial Classes in Ontario

Splendid Opportunity Open to All Engineers in Province Who Seek Higher Certificates

THE Industrial Education Act of 1911 made provision for the teaching of industrial and technical education in the schools of Ontario. Since that time great progress has been made in establishing both day and evening schools and the arrangement of courses of study to meet the needs of those persons already working in industry or those intending to enter upon industrial pursuits as a means of livelihood.

The Technical Education Act of the Federal Government of 1919 set aside $10,000,000.00 to cover a period of ten years for the assistance of the Provinces in establishing and maintaining schools and courses for the study of technical and vocational work.

These two Acts co-ordinate in such a way that any Secondary School Board may establish courses in vocational subjects and by complying with certain regulations regarding teachers, equipment, accommodation, etc., will receive assistance approximating 50 per cent. of the cost of operating. This assistance covers both expenditures on approved day and evening schools.

35,000 Enrolled

The number of schools has increased from one day school and eight evening schools, with an enrolled attendance of less than 4,000 in 1912, to thirteen day schools and fifty-six evening schools, with an enrolled attendance of approximately 35,000. There are over 1,000 teachers now engaged in teaching in these schools.

The evening schools are of special interest to employed persons who wish to obtain further knowledge and training in any trade or calling. Where day technical schools are established, it is possible to offer a wide range of work for evening classes. The courses are more limited where no special accommodation is provided. The subjects offered in the schools depend largely upon the demand. It has been the custom in many municipalities to provide a teacher and accommodation for any group of students who may desire instruction in any particular subject providing the number of students is large enough and the equipment is available.

Have Wide Variation

The classes in evening schools have a very wide variation, depending upon the needs of the community. In Technical and Industrial courses the subjects taught are usually:—Electricity, Mechanical Drawing, and Machine Design, Stationary Steam Engineering, Shop Mathematics, Woodworking and Carpentry, and Automobile Mechanics.

The classes for stationary steam engineers have grown considerably since it became necessary for engineers to obtain certificates to qualify them for positions in power plants. During the past season one hundred and twenty-six engineers have been enrolled in six classes as follows:—

Toronto	56
St. Catharines	20
Hamilton	18
Fort William	11
London	11
Timmins	10
	126

The Vocational Branch of the Department of Education co-operating with the Board of Examiners of Stationary and Hoisting Engineering have now in course of preparation a bulletin covering the work in arithmetic and engineering required for fourth class, third class, and Hoisting Engineers' Certificates.

Will Issue Bulletin

This bulletin is arranged in the form of lesson units to aid the teachers and students in preparing for these examinations. This bulletin will be published and issued for use in vocational evening classes this year.

The teacher is usually a practical man employed in a power plant in the locality and is selected because of his advanced knowledge of the subject and its practical application. The charge for enrolment is only large enough to insure that the student is sincere in his application.

This opportunity is open to all men working as steam or hoisting engineers who wish to prepare themselves for a higher certificate or to take special instruction along some branch of steam engineering. The Technical Branch of the Department of Education is anxious to promote this work, as the benefit of having efficient engineers in the industries of Ontario is evident to all.

Book Reviews

The Dynamo, Its Theory, Design, and Manufacture,—sixth edition, by C. C. Hawkins, is an authoritative work covering the present-day principles and practice involved in the production of all types of D.C. generators. Typical designs are fully discussed and every part of the generator, and the methods of construction, are illustrated by photographs of modern equipment. This book is of interest to the designer, and also to the operating engineer who should know in every detail the "Why" and "How" of the apparatus in his charge. The new edition is in two volumes. Vol. 1, with 610 pages, priced at $6.25, and Vol. 2, with 322 pages, priced at $4.50. Messrs. Pitmans Ltd., of 70 Bond Street, Toronto, are the publishers

Generating Power at Canada's Pacific Gateway

By GEO. R. ARCHDEACON, A.M.I.E.E.

Empress Hotel, Victoria, B.C., Equipped With Modern and Efficient Steam, Electrical, Heating and Ventilation Systems for Those Departing in Search of Adventure in the Orient

FACING the Pacific Ocean, within a few miles of the extreme western edge of Canada, stands the Empress Hotel, Victoria, B. C.

It is the first thing to catch the eye of all travellers approaching the Dominion on the Pacific Ocean, and it is the last link with home to those departing in search of adventure in the Orient.

And as the adornment of this hotel may be considered the last word in good taste and refinement, so may the power plant and power house be accepted as modern, efficient and complete.

J. B. Benty is the chief engineer. He was born in Bristol, England, and to fit him for his profession his parents apprenticed him early in life to the century old established firm of Peckett & Sons, Atlas Locomotive Works, Bristol.

Mr. Benty served a five years apprenticeship, finally spending two years in the drawing office, to fit himself for future responsibilities. In addition to this he filled in his spare time with special studies at the Technical Institute.

Was Junior on "Tramp"

With this training and experience as his capital, he secured a position as a junior engineer on one of the "tramp" steamers which appear at regular intervals in the port of Bristol.

After amassing considerable experience on such ships, Mr. Benty sat for his 2nd class Board of Trade certificate, and was successful. Although his scientific training and experience fitted him in every way to compete for a higher grade of certificate, the law demanded that he return to the sea, to occupy the position of 2nd engineer for a period of not less than twelve months before he could offer himself for examination for the higher grade certificate.

Subsequently he occupied the position of chief engineer with the Elder Dempster Steamship Co., and later with the C. P. R. Ocean Services, being chief engineer of the *R. M. S. Monteagle*, which rendered valuable services to the British Government during the World War.

The steam, electrical, heating and ventilation system of the Empress Hotel were installed under the supervision of Mr. Benty, and upon its completion the C. P. R. retained his services as chief engineer.

In passing it may be mentioned that Mr. Benty is a regular reader of "Power House," holds it in high esteem and encourages all members of his staff to read it regularly.

Houses Steam Laundry

The power house is situated behind the hotel a distance of 100 yards. It is a solid brick building about 100x100 feet and in addition to the steam plant, houses the steam laundry.

The engine room is a well lighted and well ventilated room 75 ft. long and 36 ft. wide.

The electrical power plant consists of three Allis Chalmers compound wound dynamos, each 75 K.W. 115-120 volts, 625 amperes at a speed of 275 revolutions per min. These are six pole machines, with six brush arms on the brush rocker, direct connected to 100 h.p. Robb-Armstrong horizontal engines, totally enclosed, with sensitive fly-wheel governors.

The switchboard is made of grey marble and is 22 feet long and 8 feet 6 inches high. As it is for controlling a two wire system, a middle wire panel is not required.

Two Linde Compressors

At the far end of the engine room there is a railed off space about three feet below the level of the engine room. Within this space are the distillers and the refrigerating plant, consisting of the following:—

> Two ten ton Linde ammonia compressors, each driven by a steam engine, the suction pressure being thirty pounds, discharge pressure 100-150 pounds. All the gauges for this plant are mounted high up on the wall and are about 15 inches in diameter, being easily visible from all parts of the room.
>
> Two sets of condenser coils, each pipe being eighteen feet long by two inches diameter, each of these banks of coils is fifteen pipes high.

The distilled water plant is operated by the exhaust steam from the main engines. There are two distillers with a capacity of about ten tons of distilled water per day. In addition, the water passes through a filter bed consisting of layers of charcoal and fels-spar.

Passing down a flight of about twelve steps we come to the pump room. The various pumps are well arranged, care having been taken to give plenty of working space behind each pump, so that repair operations may be conducted from either side. The pumps are as follows:

1 Weir Feed Pump (Vertical)	8"x5½"x12"
1 Weir Feed Pump (Horizontal)	8"x6"x12"
1 Darling Feed Pump (Horizontal)	8½"x5½"x10"
1 Burnham Vacuum Pump	8"x10"x12"
1 Blake Vacuum Pump	8"x14"x12"
1 Underwriters Fire Pump	14"x8"x10"

inlet 75 lbs. and discharge at 160 lbs. This is a displacement type and has a capacity of 500 gallons per minute when working at 70 revs. per min.

Oil fuel was used in this plant for a period of seven years, from 1913-1920, the oil utilized being Californian crude oil with a calorific value of 18,000 B.t.u.

40 Barrels Per Day

The average consumption was forty barrels per day, each barrel having a capacity of thirty-six Imperial gallons with an approximate weight of 350 lbs. of oil per barrel, or a total of 14,000 lbs. of oil fuel per day.

The oil was atomized under pressure and blown through a special ejector where it picked up the necessary amount of air. The quantity of air could readily be adjusted by movable ports in the side of the ejector. This rendered very satisfactory service, unfortunately however the market for oil fuel was so unstable and prices were subject to such wide fluctuations, that the problem ceased to be an economical one and consequently was discarded.

In this particular case the price fluctuation was as follows:—original price, ninety-six cents per barrel. Maximum price reached $3.45 per barrel. Price prevailing during January, 1923, $1.50 per barrel.

In view of such wide fluctuations Mr. Benty decided to return to a fuel with a lower calorific value but a more stable price.

Boiler House Lofty

The boiler house is a fine lofty room about 50 feet by 40 feet with an inclined runway down to the coal bunkers. Steel roller shutters close off the outer sides of the bunkers, permitting the boiler room to be kept snug and dry during rain storms and bad weather, whilst during the heat of the summer they are left open to admit plenty of fresh air and keep the place cool and comfortable for the staff.

The plant consists of the following:

> Three horizontal return tubular boilers, cross connected duplex header system of tubes. Each boiler is 157 h.p. working pressure 125 lbs.
>
> 1 Babcock & Wilcox water tube boiler with 70 tubes 16 feet long by four in diameter, Working pressure 125 lbs.

All the firing is done by mechanical stokers, each boiler being equipped with Jones Underfeed Stokers.

There is a balanced forced draught system fitted to each boiler by the B. F. Sturtevant Co. This is operated by a vertical steam engine and also a 10 h.p. D.C. motor with a belt drive is maintained in readiness in case of a breakdown.

This system appears to be giving very satisfactory results judging from the average of the CO_2 Recorder.

Average Results Good

There is a Uehling CO_2 Recorder and the average results appear to be 12 per cent. CO_2.

Mr. Benty has introduced a system of paying a bonus to his firemen, based upon the percentage of CO_2, thereby encouraging them to so regulate their firing as to obtain a higher degree of combustion. A special bonus acount is kept and totalled up each month; each fireman must show a record of not less than 10 per cent. CO_2 and not more than 12 per cent. to qualify for a bonus.

The fuel used is washed pea Ladysmith Coal with an ash content of about 15 per cent. and a calorific value of about 11,500 B.t.u. The fuel consumption is 300 tons per month.

The boiler feed water is all measured by a Venturi Water meter, and complete records are made. There is a daily log showing all possible details of operation and maintenance costs. From these it was observed that the monthly total of feed water for the boilers was 5,000,000 lbs. per month.

Seeing that the monthly coal consumption was 300 tons, this would be a total of 600,000 lbs. of coal. In other words 600,000 lbs. of coal evaporated 5,000,000 lbs. of water, or 1 lb. of coal is evaporating 8.35 lbs. of water.

The ashes are handled by an American Steam Ash Conveyor, being discharged into a concrete tank with a capacity of 12 tons and mounted on an iron frame work. The open body is then placed on the five ton truck and it is run under this ash tank, a sliding door in the base of the tank is opened and the ashes caught in the body of the truck and carted away as required.

The steam jet discharge on this conveyor is 2½" pipe terminating in a nozzle of ⅝".

Stack 120 Feet High

The chimney stack is of brick construction and is 120 ft. high, the dampers are all hand regulated and there are numerous draught gauges connected to the flues to permit the firemen to keep a constant check on their condition.

The feed water is obtained from Sooke Lake, about forty miles distance, and is of excellent quality for evaporation purposes. This is heated by a Webster feed water heater, which treats all the feed water and delivers it at a temperature of 175 degrees.

A special main supplies steam to the laundry at 100 lbs. pressure, and this operates the washing machines, ironing machines, and dryers.

There are four electric elevators, 1 hydraulic elevator, and 3,500 electric lights in the hotel, and the average energy consumed by each lamp is 40 watts. Supposing, therefore, that all these lights were burning at one time there would be a demand on the power house for electrical energy of 140,000 watts for the electric light service only, or a total of 182 h.p. of energy.

The power house is connected to the hotel by means of a tunnel. This is 7 ft. 6 ins. wide and 8 ft. high, and is made of concrete well drained. The electric mains are run down one side of the tunnel, supported in iron troughs laid on angle iron bearers. On the opposite side are the steam heating mains, compressed air, and vacuum pipe lines for the various hotel services.

In conclusion it may be of interest to readers of *Power House* to know that the C.P.R. has been granted a further exemption from local taxes by the municipality of Victoria, upon the understanding that they inaugurate a tea garden, cafe, and amusement park on a vacant piece of land within half a mile of the hotel.

In view of this undertaking it will be necessary to increase the size of their present electrical plant, and Mr. Benty estimates that he will require an additional boiler, steam engine and dynamo, some time within the next eighteen months as well as the other accessories that go toward the efficient operation and completion of such an extension.

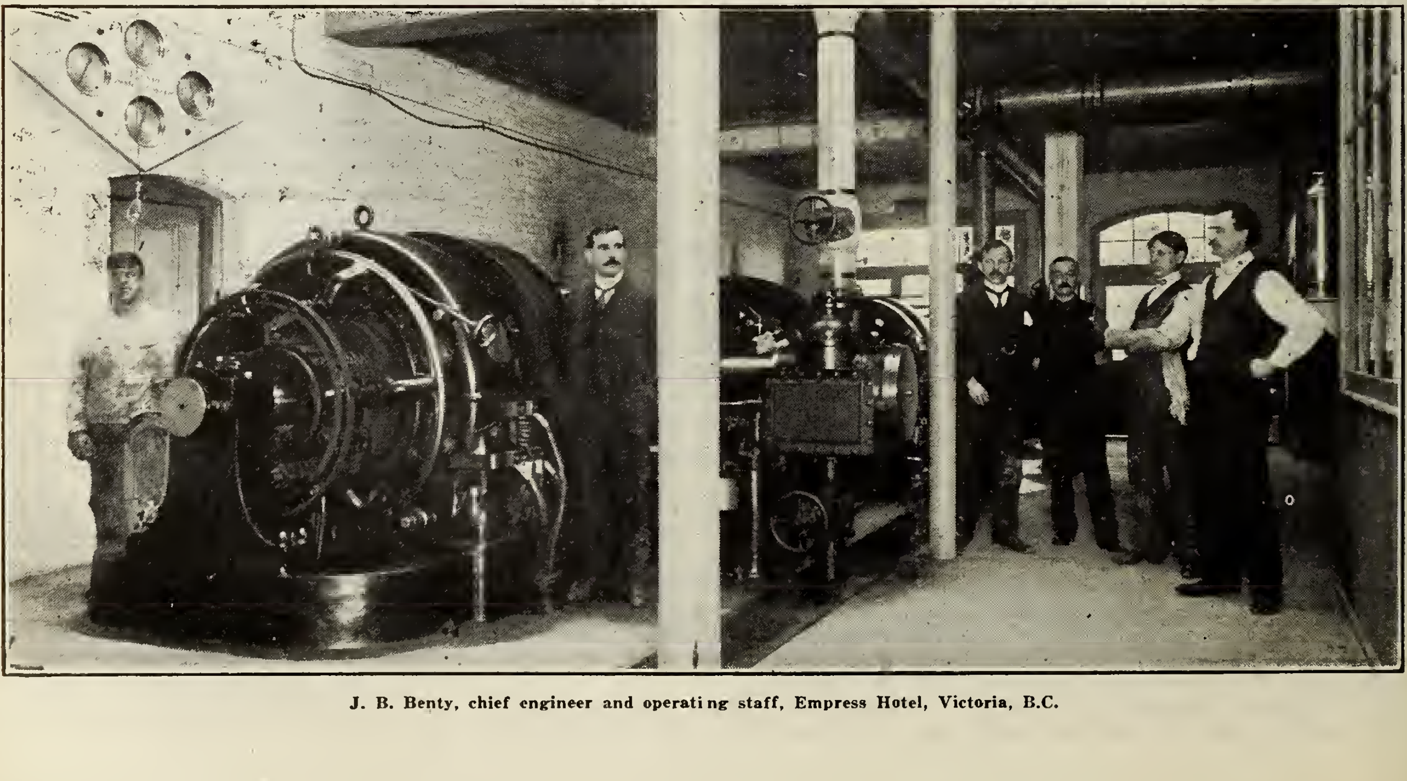
Water jackets around bearings furnish means of carrying away the heat generated by friction in proportion to the pounds of water multiplied by the temperature increase in deg. F., the specific heat of water being unity.

Self-oiling bearings have the merit of using the same oil continuously without waste other than by slight vaporization and creepings, but proximity to a heated bearing keeps the oil at a higher temperature than it is at its best for lubricating.

The current is that in any lead and the voltage that of any phase except in the case of a two-phase, three-wire system, where the current is that in either outside wire and the voltage that between either outside wire and the common wire.

To operate a compound-wound dynamo as a motor it is necessary to reverse the series-field connections, otherwise the series and shunt fields will oppose one another, resulting in a small starting torque and poor speed characteristics.

The law of fluid motion is that the force required to shear a layer of fluid, of a given area of the element in plane of shear, and thickness, normal to the plane of shear, is directly proportional to the relative velocity (surface speed of journal) of the two surfaces and to the area, and inversely to the thickness of the fluid.



J. B. Benty, chief engineer and operating staff, Empress Hotel, Victoria, B.C.

Remote Control of High Pressure Steam Lines

By PETER PAYNE DEAN,* A.S.M.E.

An Explanation of the Construction of Various Protective Devices, Values and Motor-Control Systems That May be Obtained in the Open Market To-day

THIS article is intended to bring out need of protection other than that of hand-operated valves for high-pressure steam lines in case of failure of pipe or fittings, and deals with the remote operation of various types of valves by electric motor or steam piston in order to quickly and safely stop escaping steam.

It is based on a very careful study of valve construction and methods of power operation during the last few years, and on experience gained with more than a thousand electrically operated valve installations which the author has designed and placed in large power generating stations.

Steam pressure as high as 350 lbs. per sq. in. with 700 deg. Fahr. total heat are now frequently encountered, and no doubt 500 lb. will soon be standard practice. Under such pressures every piece of valve, piping, and fitting metal will be subjected to an excessive strain, which, when coupled with high temperature. may produce a result akin to metal fatigue, about which we have little knowledge and even less experience. Further, no safe standard has been universally adopted for 500-lb. steam fittings, bolts, flanges, expansion loops, etc., but this will very probably come after more exhaustive time tests.

Gives Protection

The protection of human life, however, should be the first consideration, and after that, continuity of plant operation and protection of property; and surely all will agree that protection beyond that found in the average plant is necessary.

We never think of asking an operator to manually trip an oil switch, which is done from the central switchboard; therefore, why ask him to mount a boiler or scramble through dark galleries to shut off a steam break when it may be done from a safe point by merely turning a switch?

We can only make every attempt to prevent failure by careful design, and then provide, as a matter of precaution, the best possible safeguard if it does happen.

The master valves should be those nearest the boiler, and either the automatic stop checks or gate valves in the boiler lead. Valves at this point protect the complete piping system and would not be affected by mechanical movement of a broken line, which would possibly throw excessive strain on a gate valve, causing it to jam.

Automatic stop-check and boiler-lead gate valves are seldom above 10in. in diameter and without doubt can be closed in from fifteen to thirty seconds, so that any or all of the boilers may be cut out at will.

Unless all the boilers are isolated there would be a reverse flow from the header back through the break, so that a maste valve is also necessary in the boiler lead at the header, which in any event is usually included. Closing both the boiler-lead valve and this last-mentioned valve completely isolates one boiler.

Valves are Needed

Boiler-lead valves are suggested for three very good reasons:

They protect the whole system of piping from the superheater and are well located for power operation.

Peter Payne Dean was born in Staffordshire, England, and his early education was received at the English public schools. Later he attended the Birmingham Technical School and the City and Guilds of London Institute.

In 1909 he went to the United States and became connected with the Diehl Manufacturing Company, of Elizabeth, N. J., acting as sales engineer until 1913. During this time he was responsible for the electric equipment of many large industrial plants, and he completely developed an electrical dynamometer which was extensively used in the scientific testing of internal-combustion engines.

In 1913 he was engaged by the Ingersoll-Rand Company, and in 1914 by the Cutler-Hammer Manufacturing Company, which latter concern took over his patents on valve control. From that time to the present his whole work has been devoted to the design and manufacture of valve-control systems and remote-control devices for central-station use.

If a bad fracture should occur, it would be almost useless to endeavor to locate it and sectionalize the header to stop the flow, on account of the tremendous volume of condensed steam and consequent confusion.

There is no certainty whatever that header valves above 12 or 14 in. in diameter will close under open-end conditions on account of their construction to withstand such strain.

The principal argument against emergency closing off of the boilers is that the plant would be completely shut down. In the author's opinion, if a bad break occurs its location cannot be determined until almost the entire steam supply is stopped. As soon as the break is located, the sectionalizing valves may be brought into play and the boilers quickly brought back on the line.

Even though large header valves can be closed from a distance, the author nevertheless believes that the quick and safe way is to shut off the boilers in sections until the break is stopped. Incidentally, with any remote-closing scheme the boiler safety valves should be piped to a header and blown to atmosphere, as in the event of a boiler shutdown they would all blow together.

Some arrangement also of an auxiliary header should be worked out to supply the boiler-feed pumps, as well as a scheme for shutting down the draft fans.

Power-operated header valves of large diameter may be depended upon to stop a very bad fitting blow or gasket leak, so for this reason and also for convenience of operation they should be provided with remote control.

To close an 18-in. high-pressure gate valve requires two men for a period of at least fifteen minutes, including transit to and from the valve, not to mention the physical effort-necessary and the danger of penetrating a steam-laden alley with very uncertain conditions under foot. For years engineers have applied power operation to sash monitors, ash gates, dampers, and other auxiliaries, but seem to have entirely overlooked the poor old steel sentinel that stands guard over the main artery.

Great care is taken to see that main-line valves are tested for tightness and that they are strong and rugged, presumably for assurance that they will not fail during operation or when an emergency arises. Who knows, however, whether they can be even reached in case of trouble? Therefore, why not turn them into real protective devices by providing remote control? It should not take much of an argument to convince those in charge of expenditures that it is worth the money.

Fig. 1 shows a typical existing boiler and piping layout in which electrically operated valves are employed. Complete isolation of one boiler from the line may be made by closing any pair of valves A, B, either singly or from one switch, but this of course leaves the boiler-lead lines unprotected. Further protection may be accomplished by electrically operating the non-return valves shown and closing them together with valves A, B, in order to prevent reverse flow from the header.

Locate Switchboard

Since any remote-control system must of necessity be electrical, the design and placing of a central switchboard must be carefully thought out. The location should be as near the main means of exit as possible, as plant operators in case of trouble will move toward this point. With the open air in view, a man is more apt to regain his composure and presence of mind than when called upon to act hurriedly and then bolt for his life.

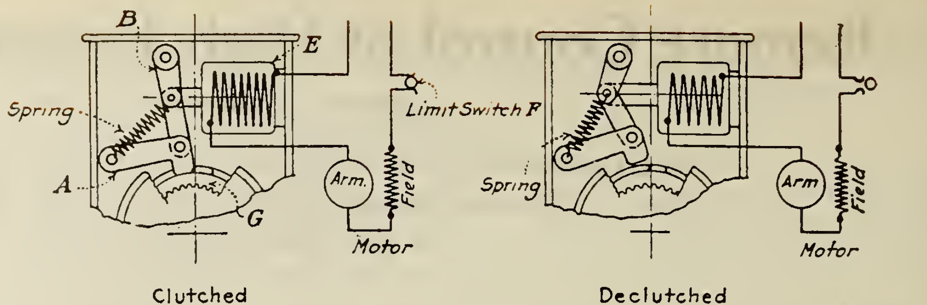
---

*Extracts from a paper presented at the Spring Meeting, Montreal, Canada of the A.S.M.E.

Such stations should never be placed in steamprof vaults adjacent to the boiler room and without means of safe exit. They will be useless in emergencies, as the opertors will not travel in that direction.

The operation of switches to shut the valves should be as simple as possible, preferably by breaking a protective glass window and pushing a button.

Under no consideration is it safe to open master valves from a remote point which may be opened locally, eitner by hand or electrically.



SKETCH SHOWING PRINCIPLE OF OPERATION OF A SECOND TYPE OF VALVE-CONTROL UNIT

Two Types

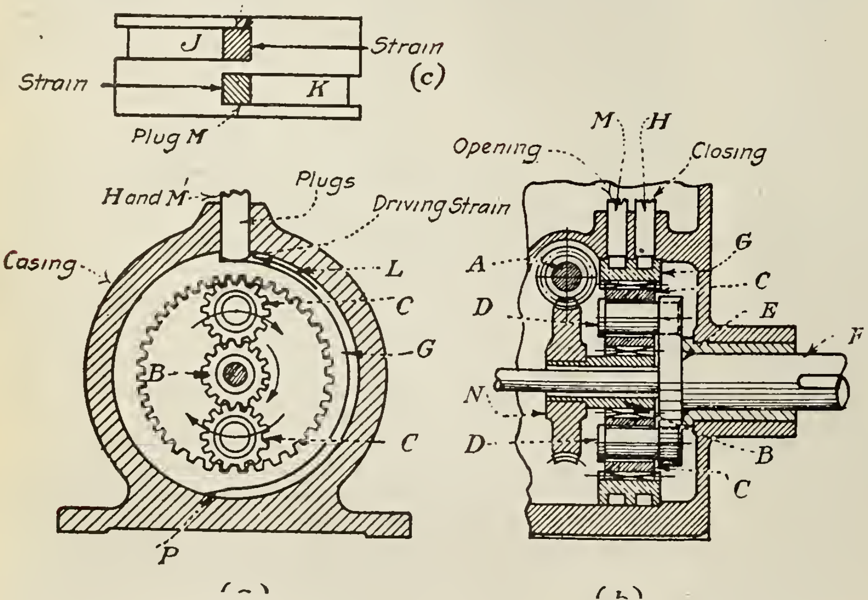
There are two types of quick-acting valves, the straight triple-duty, and the piston-operated trip valve, both of which are of the globe type. The former is a combination of non-return, stop, and "automatic closing on drop of line pressure," performing therefore the three duties. Engineers have not taken kindly to line protection upon drop of pressure; therefore the third duty is operated by an electrically controlled pilot valve admitting steam on top of the closing cylinder. This valve depends upon the excess-area piston forcing the disc to its seat against the pressure. The straight trip valve closes with the pressure and is remotely operated by a olenoid magnetic latch.

This valve is used mostly as an additional emergency turbine stop upon overspeeding, being placed in the turbine lead between the header and throttle trip valve. On account of its somewhat complicated construction, it is hardly suitable for line protection. The triple-duty remotely controlled valve would seem to be the logical type for quick closing, provided that it can be made to close against the extreme velocity which would result with an open-end line blowing to atmosphere and would possibly reach 50,000 ft. per min., depending upon the friction loss in the pipe between the header and the boiler. The action in this case would not be that of a non-return automatic check valve which actually closes due to the reverse flow, but the disk would be forced on to its seat against an extreme velocity in the opposite direction and the action would be somewhat akin to that of stopping a high-pressure nozzle with one's finger. Valves of this description are generally closed by pressure being admitted to the top of the excess-area piston, but test data on closing under extreme velocity conditions do not seem to be available, and until they are, much cannot be said.

A high steam discharge is very apt to carry over slugs of water, and there may be some doubt as to the advisability of instantly closing a valve under this condition. It would seem that a closing time of ten to fifteen seconds would be safer.

Motors Close Valves

Electrical operation of non-return valves was first suggested by the author and has been adopted by many leading engineers. The operation is the same as that required on the triple-duty design, with the exception that the valve stem is driven by a motor provided with reduction gearing. Their action under most extreme conditions is positive, provided that the motor control is of the proper design and application. The valves are ideally located with respect to line protection, being directly at the superheat outlet and where vibration due to the whip of a broken boiler lead would not be excessive on account of the valve being securely anchored. They close easily under normal conditions, and for emergency closing should be provided with ball thrust bearings to eliminate the closing friction as much as possible. The control unit should be bolted directly to the yoke and geared to the stem through the yoke nut which is of the rising-stem type. The travel of the disk is not more than one-quarter of its diameter, so that quick closing is possible. Although ruggedly built, this valve will not stand much jamming, and therefore calls for a special type of motor control to prevent it.



MECHANISM OF ONE TYPE OF THE AUTHOR'S VALVE-CONTROL UNIT

Disks Must Be in Contact

There is only one safe point of closing, and that is when the disks and seats are in perfect contact; to effect this the motor drive should have an automatically operated mechanical clutch completely disconnecting the high-speed armature and gears from the motor at the moment of closing, thus eliminating its momentum and allowing the motor armature to come freely to rest. Without this clutch the limit switch must be set to stop the motor before the valve reaches its seat, and a certain amount of drift due to the momentum of the armature and gears must be depended upon to seat the valve.

This drift depends upon the resistance to closing, which distinctly varies with line conditions; for instance, when the valve is closed with balanced pressure and there is no flow in the boiler-lead line, there is no resistance to the disk and the electrical limit must be set to trip just at the point of closing so that the disk can drift into its seat.

Assume, then, an open-end pipe condition with steam blowing to atmosphere, during which the disk encounters excessive resistance. The moment the electrical limit opens, the velocity will overcome the momentum and act as a brake, thus causing the motor to stop instantly and before the valve is actually seated.

The non-return or globe valve must seat tightly and has no leeway to travel as has a gate valve. Therefore it should be made to seat tightly under all conditions and without jamming or strain.

Motors Get Little Care

There is hardly a piece of machinery in the power plant that is subjected to such extreme operating conditions as the motor-controlled valve:

a It is usually located in an out-of-the-way gallery and covered with coal dust, and in a temperature ranging between 150 and 165 deg. fahr. which necessitates special heatproof motor-coil insulation.

b It is thrown directly across the line without the aid of starting resistance so that the full voltage is impressed upon the windings, and at the same moment the motor may be called upon to exert its maximum mechanical effort in unseating a tightly seated valve

c It must be small and compact, automatically lubricated, and entirely steamproof and waterproof.

d Periods of inoperation range from the minimum of one week to, say, three months, during which time plant conditions may be such as to prevent its operation; and it is expected to function perfectly, even though it has not been tested over this extended period.

e Steam from a leaky gland may be allowed to blow freely on the control unit for an indefinite period, and to withstand this it must be impregnated.

In case of piping rupture it is more than likely to be enveloped in condensed steam, and just at this time it will be called upon to exert its maximum mechanical effort to close the valve.

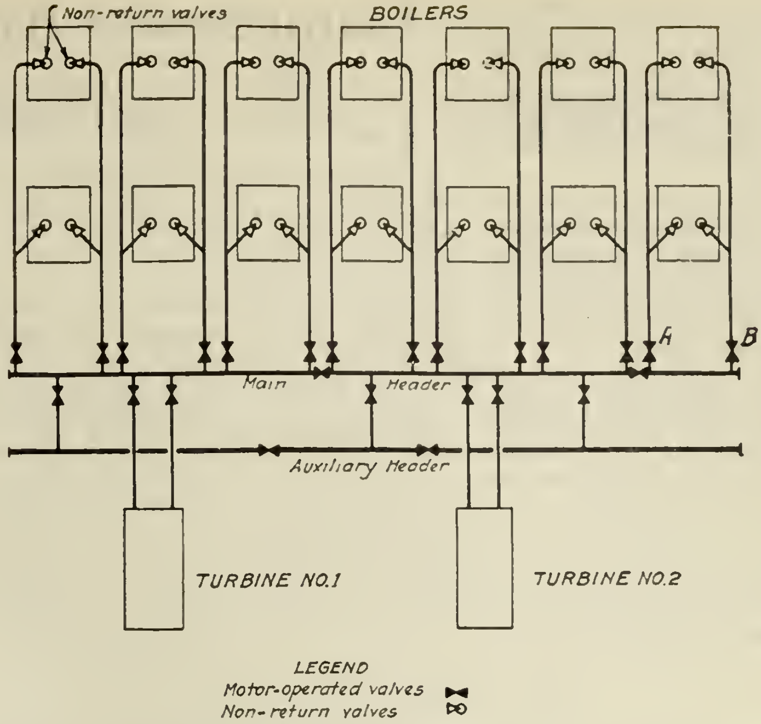
The duty on such equipment is extremely severe and without doubt necessitates much special construction. The motor must be of the totally enclosed type and provided with ball bearings of excessive diameter. It should be bolted directly to the reduction-gear casing, leaving no coupling or high-speed shafts and bearings exposed. It should be series wound with such characteristics that it will automatically slow down upon the application of load caused by the valve disk passing into the seat. This is the surest means of protection against cutting of the disk and seat rings.

The reduction gears should be of heat-treated steel on account of their compactness and the excessive strain that may be applied, and should be continually immersed in oil. Any oilless or self-lubricating type of bearing for either the motor or slow-speed shaft should be avoided on account of its inability to withstand excessive heat, long periods of rest, and the accumulation of dust in the bearing.

On account of the excessive drift of the motor armature and gears after tripping, a declutching device should be provided to enable the valve stem to be stopped automatically at a pre-determined point without jamming. In the same casing should be provided a self-contained electrical limit which is capable of breaking the main motor current without arcing and so geared that operation of the valve by hand will not throw it out of adjustment.

The casing should be provided with one conduit opening arranged for making a steamproof joint between the internal connections and the line, and all internal connections should be of asbestos-covered heatproof cable.

Control of the valves may be effected from either one point or from multiple points by the aid of a totally enclosed dust-proof reversible drum switch capable of reversing the armature connections.



Boiler and Piping Layout of a Power Station in Which Electrically Operated Valves Are Employed

The stations should be provided with lamp indication showing the full open and closed positions of the valve at all times. Such a control switch should be provided with a lock, an emergency glass window, and a hammer.

Operator Has Full Control

For multi-point control an interlocking system should be provided so that the first operator to reach a valve will have full control, even though other control stations are operated at the same time and in reverse directions. The best way of accomplishing this is to provide an interlocking relay panel so that only one switch may be closed at a time, and further protection by an electrical interlock consisting of a magnetic system whereby each control-station drum will be retained in its proper operating position and will automatically return to the "off" position at the opening or closing point of the valve.

In every case both poles of the electrical circuit should be interrupted when the switches are in the "off" position. Single pole break is dangerous, as a ground may cause the valve to either open or close and produce very serious inconvenience.

Current Must Not Fail

A valve-control system should be connected to the most reliable source of current in the station, which is either the direct current exciter or switch-control battery circuit, as it is equal in importance to any piece of auxiliary machinery. The voltage should not exceed 250, firstly, because direct-current battery circuits of this voltage are standard, and secondly, because higher voltages would cause an unnecessary strain on the very closely packed windings. Valve motors are thrown directly across the line without resistance and encounter at the same moment their full mechanical strain due to a tightly seated valve.

Each valve should be provided with a local control station, mounted at some point from which opening and closing the valve may be observed. Preferably there should be two points of control for each valve, one in the boiler room close to the door leading into the turbine room, and the other at a safe point unlikely to be affected by steam flow. Where a centralized control board is adopted, the second point of control may be mounted in the turbine room, and for the closing of turbine-lead valves the control may be mounted on the turbine gage board.

Protect Cables

All conductors should be suitably protected by fuses having a capacity equal to the full-load starting current of the motor, and fuses rather than switches should be provided for disconnection. The cable should be chosen according to the location, and for the operation of high-pressure superheated-steam equipment, should have an asbestos heatproof covering.

It is a good plan to end the rigid conduit within 3 ft. or so of the control unit, and from that point use a flexible loop of Greenfield or similar duct. This will allow considerable vibration in the pipe line without affecting the cables, and will further enable the control unit to be freely moved.

Hand Control Essential

Handwheels should be provided in case of failure of current supply.

No declutching device should be installed between the motor and valve which destroys the relative position of valve and motor mechanism. A properly designed and cared-for valve-operating system, especially in a power plant, need never fail, and in case of possible failure at a critical moment the valve may be closed by the handwheel, through the gears and motor, in almost as short a time as when the parts are disconnected.

The great danger of a declutching device is that it is very apt to be left disconnected with no means of showing its position at the control station, and that it introduces a non-foolproof feature by providing a piece of mechanism that can be tampered with by any unauthorized person.

If such a device is insisted upon, it should be a self-contained part of the mechanism and operated externally by the aid of a wrench. Further, it must be so arranged that positive indication of its position must be noted on the indicating lights at the control station.

Every electrically operated valve should be opened and closed at least once a week, preferably under load conditions if possible, and an examination of the internal parts should be made at least once a month and all records of such tests and examinations kept on file.

When transformers are to be operated in parallel, care should be taken to see that they have the same polarity and that they have the same characteristics. To determine whether the polarity of two transformers is the same, connect the corresponding secondary terminals through small pieces of fuse wire and close the primary circuit. If the fuse blows the connections must be reversed; if not, the transformers are of the same polarity.

Announcements

Geo. J. Soucy, of Toronto, has been elected general secretary of Dominion executive, Canadian Association of Stationary Engineers. Mr. Soucy is now engaged in special work in connection with the betterment of power plants and the supervision of operating conditions. He has had twenty-five years' experience in the design, construction and operation of all kinds of plants. His method of procedure is believed to be unique in that he always insists on a personal inspection of the boilers to determine the actual working conditions.

Mr. Soucy, it is claimed, effected a saving of $250.00 per day in one plant of 4,000 h.p. capacity by simply regulating the drafts and dampers for a given thickness of fire. He has twice been the Canadian representative to the convention of the National District Steam Heating Association, which formulated rates during the war and standardized the methods of underground construction.

Compressed Air Main Leakage

Leaks in Air Lines Hard to Detect—Flanges Superior to Screw Joints—Use Proper Packing

AS FAR as leakage is concerned, compressed air is very different from steam or water. Both the latter substances are easily seen, and any escape is therefore immediately apparent. In the case of steam the pipes are always accessible and the remedy is soon applied. A water leak is easily found on account of the inconvenience caused by the appearance of any considerable body of water in one locality. If the pipe is underground, the earth gets very sodden and accumulations of water appear on the surface; in this case also the remedy is simply applied. With compressed air, however, the problem is more difficult, since the medium employed cannot be seen, and in places where a great deal of noise is an everyday occurrence it cannot be heard escaping, so that undetected leakage is very possible.

When pneumatic pipes are laid underground any small leakage may go undetected; but if any considerable volume of air escapes, the first heavy rain causes a furious bubbling on the surface of the ground just above the leak. During dry weather it is a good plan—that is, if the surface is not covered by cement—to pour periodically several pails of water over the ground above those pipe flanges where leakage is most likely to occur. Such places are at sharp bends in the pipe-line, and where the pressure on the earth due to foundations and buildings changes suddenly. This method can be made infinitely more sensitive if, when the pipes are being laid, the space above each flange is filled in with ashes instead of earth. In this way the smallest amount of truant air quickly rises to the top and is detected.

In the case of pipes which are above ground other methods have to be adopted. Where the pipes pass through buildings an excellent method is to pass a lighted match or candle round the flanges, when even the slightest leak will be betrayed. In the open, where a light is impracticable, a very good method is to wet one's hands, and, moving from flange to flange, to pass them round each at about half an inch distance so that any leak must blow directly upon them. In this way the presence of the smallest issue of air causes a slight evaporation on the hand, and a consequent coldness which is very readily felt.

For testing large air receivers for leaks an excellent method is to have the seams periodically brushed over with a soap solution. It is wonderful the number of small leaks which come to light in this way. These only require a tap from a caulking tool to be rectified. In a large system, if all these small escapes are allowed to accumulate, the leakage soon assumes great proportions—that in a large shipyard having been known to reach 25 per cent. of the total output from the power-house.

Having enumerated some of the leaks which may be expected in a large or small system, attention had better be turned to their remedy, or, better still, their prevention. First, then, as to joints in the pipe-line. Flanges are much superior to screwed couplings, on account of the greater ease with which they can be adjusted.

Then, again, when dismantling for repairs, small bolts are easier to unscrew than a large-diameter ferrule, which is apt to get out of shape and jam. Last, but not least, flange joints will allow of slight curves being made in the pipe lines, whilst screwed couplings will not. For jointing material leather has been tried, but the great variations in temperature and moisture soon cause shrinking and endless trouble. Most kinds of patent steam and water jointing will stand a first tightening up, but not a second; and all these joints are fairly expensive. A very successful method which has been in use for some time now is to face the flanges in ridges and use a medium grade of oily millboard. The ridges are easily machined with a quick self-act and a tool of the type shown in the figure. By this means the millboard, which should be "doped" with a thin oil if not greasy enough, is forced into a series of small rings, which act like miniature hydraulic leathers. This type of joint can be tightened up time after time, is cheap, and above all very reliable. Results show that if these joints are initially quite tight and followed up with a half-turn or two for a day or so until quite set, no trouble need be expected from repeated heating and cooling, or from moisture or vibration.

Oil containing paraffine will emulsify, in warm water, more readily than if without, and on being allowed to stand in a glass vessel, will show a whitish film between the oil and water when cooled.

Selecting oils may be best done by trial, like the proverbial pudding, and when a satisfactory mixture is found, have it analyzed and require the same ingredients in the same proportions in future purchases.

Flashpoint determinations have no definite connection with lubricating power. None of the lubricating oils on the market have a dangerously low flashpoint. For gas-engine cylinder lubrication a reasonably high flashpoint is necessary.

The Value Of Convention

THE annual convention of the Canadian Association of Stationary Engineers, with its accompanying exhibition of power plant equipment, has established itself as an occasion for presenting to the engineering fraternity new and better methods of combustion. The gathering last week in the Central Technical School at Toronto surpassed those of the past in the numbers attending, in the excellence of the entertainment program and in the diversity of the exhibits presented.

Apparently there has been a rejuvenescence of interest in modern combustion methods, which can be attributed, doubtless, to the fact that the problems now facing engineers of the Dominion call for advanced knowledge to bring about their correct and economical solution.

Conventions such as this, which serve to interpret and to apply economies in the art of combustion as well as to disseminate the spirit of goodwill, are valuable to the power plant industry in an even greater degree than those which exist merely to discuss commercial practices.

All who attended the C. A. S. E. convention must necessarily have returned to the boiler room stimulated and keyed to a higher pitch through hearing the experts in charge of the various exhibits explain the developments in their particular fields.

Easy Engineering Lessons

TO THE publishers of Power House comes unusual opportunity for service in being able to begin with this issue the first of an extensive series of articles on power plant operation by Captain M. B. Watson, director of the Department of Engineering in the Central Technical School, Toronto.

Mr. Watson's experience and qualifications are such that these articles should be of immense benefit to stationary and other engineers of all grades.

Commencing his stationary engineering experience at the age of fifteen years by taking charge of a night shift in a steam-driven power plant, while he continued to attend high school in the day time, Mr. Watson proceeded to the University of Toronto, where he graduated in mechanical and electrical engineering in 1910.

He has received from the above institution the degrees of Bachelor of Applied Science and Mechanical Engineer. From the above early age to the present, Mr. Watson has kept more or less closely in touch with the stationary engineer and his work. Even during the war he was employed as an officer of the Royal Engineers (Imperial) in charge of the installation and operation of pumping plants for the supply of water to the trenches in France, until he was sent back to England due to physical disability, when he was attached to the Royal Air Force as an instructional officer on internal combustion engine work.

At present, Captain Watson is chief engineer, holding a first class Ontario stationary engineer's certificate, and is in charge of the instructional work in engineering in Toronto's Central Technical School. As a registered professional engineer of the province of Ontario, he is carrying on a consulting practice along the lines of power plant design and efficiency, also on heating, ventilation and illumination. Mr. Watson is an associate member of the Engineering Institute of Canada, a member of the American Society of Mechanical Engineers, also an honorary life member of the Canadian Association of Stationary Engineers.

Men having such a combination of theoretical training, actual stationary operating experience, as well as experience in instructional work, are few and far between, and we feel fortunate in securing Mr. Watson to take charge of this section of Power House.

* * * *

Careful Reading Vital

IT IS to be feared that many Canadan engineers, immersed in the busy job of power plant operation, do not fully appreciate how much science, and it may be justly added, the technical press, have done and are daily doing to lighten the burden of their labors.

The combustion field is so vast that it is difficult for the individual to realize more than a small fraction of what is being done, whether it be in regard to the study of boilers and their behavior under the exacting conditions which apply to modern practice, or in regard to such matters as the practicability of super pressure, or the economies of various types of fuel.

What is more common than to hear an engineer say, "I have not had time to read so and so; there is so much to be read"—which means generally that he reads nothing at all.

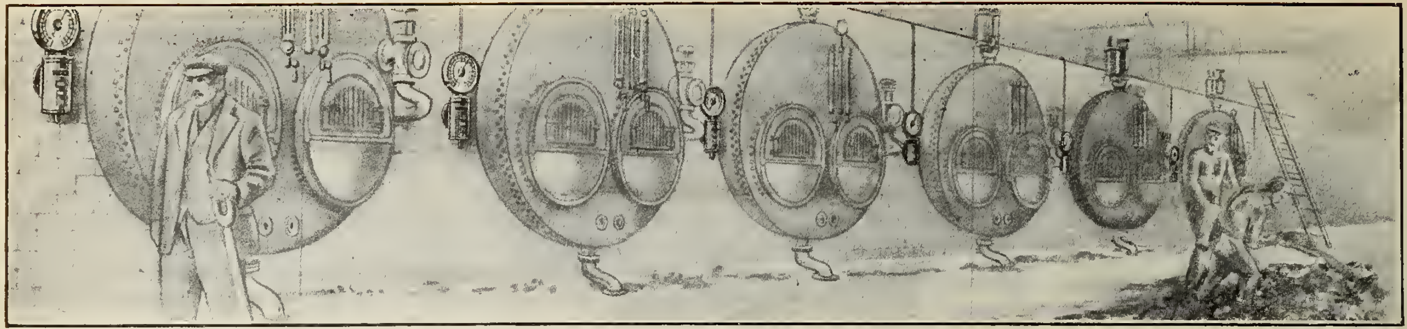
"Proceedings" are collected and filed, books are bought but only glanced at, technical newspapers are skimmed; indeed, experts do not hesitate to say that amongst the general body of engineers there is far less careful reading to-day than there was thirty years ago, although it is universally admitted that never before was it so essential for engineers to keep posted on developments in power plant operation.

* * * *

Using The Slide Rule

THE number of Canadian engineers who make daily use of the slide rule increases daily but some of the old prejudice that it is not "accurate" remains. For most purposes, however, its degree of accuracy is entirely sufficient.

It must, of course, be remembered that when using the rule for multiplication or division one cannot expect to read closer than about one part in a thousand, but on the other hand it should be remembered that the majority of the original measurements in power plant problems are out more than one part in a thousand and so the engineer who is skilled in the use of the slide rule and aware of its limitations can save a lot of time without sacrificing any necessary accuracy.



Easy Engineering Lessons in the Power House

By M. BARRY WATSON, B.A.Sc., M.E.,
Director of Engineering, Central Technical School, Toronto.

The Proper Use of the Shovel a Vital Factor in Increasing the Efficiency of a Plant With a Corresponding Decrease in the Physical Exertion Necessary

IN ALL but the largest steam power or heating plants, where the handling of all coal and ashes is done mechanically, by far the greatest part of real physical labor is expended in the shoveling of coal and ashes. Anything that will tend to decrease the amount of physical exertion or the time spent in shoveling will therefore be of value to all engineers.

The engineer who is alone in the one-man plant will be less tired at the end of his day, because of the saving of muscular exertion, and in the time saved he will be able to give better attention to the minor things which increase the efficiency and improve the appearance of his plant.

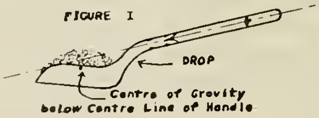
The chief engineer of a large plant who understands this work can train his firemen to carry it out in the easiest and most efficient manner, giving them more time to attend to other work which benefits the firm in saving coal, the chief engineer in getting more help on other work, and the firemen in having less coal and ashes to shovel, as well as giving them a chance to learn the more advanced part of operating work.

Objection Groundless

The writer has heard the objection put forward by some firemen that if they shovel more efficiently than the other fellow they will be given more boilers to fire, etc. This type of objection is on the face of it quite groundless, because, in the first place, it is no more exertion to fire three boilers properly than to fire two improperly; besides the chief engineer or the manager will before long single out the man who works most efficiently and will remember him when a chance for promotion comes.

Some firemen have even gone so far as to think that the most efficient firemen will be kept on the job firing while those less efficient will be given other work, possibly with promotion, when the opportunity opens. This is, of course, a mistaken idea. A reasonable chief or manager will at once realize that the best man should be promoted, and thus be given authority to instruct the poorer men in the efficient methods which he himself used, thus increasing the efficiency of the staff and the plant as a whole.

FIGURE I

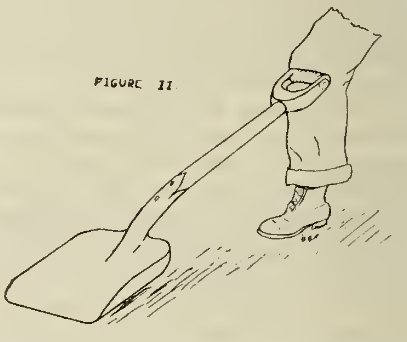


Choice of Shovel

The most important point in the efficient use of a shovel is the selection of the best shovel for the work and for the man who is to use it. There is a large variety of shovels on the market and not all are suitable for different jobs or different men. The scoop of the shovel should be large enough to hold from eighteen to twenty-one pounds of the material to be handled when the shovel is new. The shovel should be discarded when it has worn down so much that it will not hold more than fifteen pounds of material, or it might be used for shovelling some more dense material. For instance, a shovel which was worn so far that it would not hold sufficient coal might be used with economy for shoveling ore. It has been found from the results of a long series of experiments that a shovel of the above size will handle a greater amount of material in less time and with less exertion than any other size.

The lessons which will be published in this department of Power House are not a consecutive series of lessons leading up to any one Class of Stationary Engineer's Certificate, but will alternate between lessons suitable for the various classes of engineers. At the same time they will be in such form and will bring out points which will make each of them of value to all classes. For example the following article on the Use of the Shovel, while apparently a subject on which most engineers feel they are thoroughly posted, brings out some points which most engineers have never thought of. Correspondingly the more advanced lessons, while probably of greatest value to the higher class engineers, will bring out minor points which will be intelligible to and of use to engineers in even the humblest positions. Throughout these lessons the author does not propose to be didactic, but will welcome criticisms, discussions or suggestions, also requests for lessons on any particular subject. These may be sent to the author, care of the Editor of Power House, 143-153 University Avenue, Toronto.

FIGURE II



A larger shovel than this is too tiring for any but the biggest men, while a shovel which is too small takes longer to do the work, which is especially important in firing a boiler when the fire doors should be open as short a time as possible; and it is no less tiring, because, although it is slightly easier to lift a shovelful, there must be more shovelfuls moved, which means the work required to move the shovel around more times besides the energy required to move the same amount of material.

The scoop of the shovel should be "dropped" from the handle sufficiently to insure that the centre of gravity of the loaded shovel is below the line passing up the centre of the handle, as illustrated in figure 1. This prevents any tendency of the shovel to upset in the hand as well as allowing the scoop to swing slightly with the movements of the shovel which prevents part of the load falling off the shovel. This saves a lot of muscular strain on the wrists, which, though it might be corrected unconsciously while shoveling, is nevertheless tiring to the muscles and nerves.

The best shovels are those in which the metal of the scoop is fashioned into quite a long ferrule, or into long top and bottom straps extending at least a third way up and riveted securely to the wooden part of the handle.

The handle of the shovel should be as long as can be conveniently used by the fireman. A short-handled shovel makes it hard to give the coal enough force to carry it to the bridge wall, especially in a long furnace. It also necessitates the fireman standing too close to the furnace door for comfort, and makes him bend his back farther for each shovelful he picks up.

Angle is Important

The angle at which the scoop is attached to the handle is quite important. If the angle is too flat material will roll off the tip of the shovel when it is being swung. On the other hand the material will roll off over the back edge of the scoop if the angle is too great. Also in sliding the shovel along the floor at the edge of a pile, the end of the handle will be too low for comfort or for applying the necessary force easily if the angle is too flat, and the handle will be too high if too large an angle.

Naturally all firemen cannot use the same sized shovel with equal facility. The shovel should "fit" the fireman. A tall, long-armed man will prefer a longer handled shovel than a short man, and vice-versa.

To "fit" a fireman, the angle of the scoop, the drop and the length of the handle should be such that the end of the handle comes just below the fireman's knee cap, as shown in figure II, when the scoop is lying flat on the floor.

Care of Shovel

About half the exertion in shoveling is in the filling of the shovel. In order to make this part of the work as easy and speedy as possible the shovel must be kept in proper condition. The edge must not be allowed to become burred or split. When a small burr forms on the edge of the shovel, it should be hammered flat, or better still, ground off and the edge trimmed to its original shape. In case the edge becomes split, it should be trimmed or ground off to the bottom of the crack. The bottom of the shovel should be perfectly flat across the edge to the points where it turns up to form the sides.

Naturally the shovel will hold less and less material as it becomes worn away or trimmed and should be discarded when it gets too small to be efficient.

Cheap shovels often come loose at the ferrule or handle straps, and if this condition cannot be successfully remedied by tightening up the rivets the shovel should be discarded, as good work cannot be done with a wobbly shovel.

Filling the Shovel

In picking up a shovelful of coal or other material the shovel should, whenever possible, be placed on the floor at the edge of the pile and pushed under the material. Of course this is not possible when it is necessary to stand on the coal and dig into the top of it, such as starting to unload a car. If the floor is smooth the shovel will slide under the edge of the pile easily, this is because the edge of the shovel always strikes the edges of the pieces of coal, and has to raise them only the thickness of the blade of the shovel, whereas when digging into the top of a pile the edge of the shovel strikes all parts of the various lumps of coal, etc., and has to either push these ahead of it or push them aside. If necessary, in pushing the shovel into the pile, the leg can be made use of by throwing the weight of the body against the back of the hand holding the end of the handle.

M. BARRY WATSON, B.A.Sc., M.E.

To insure easy shoveling off a floor the floor must be as smooth as possible. A good concrete floor is usually the best for this purpose because the feet will not slip easily on it, while the shovel slides along quite readily. A poor quality of concrete soon wears into holes, making the shoveling just as hard as digging into the top of a pile. A good quality of paving brick makes a good floor off which to shovel if it is laid with good hard mortar and thin joints. A piece of steel plate on the floor is about the easiest thing to shovel off, but it makes a very slippery floor to walk or stand on. If steel plate is used for the coal in front of a boiler, it should not extend so far toward the boiler that the fireman has to stand on it.

While considering floors on which to shovel, it should be kept in mind that a clean space should be kept on which the shoveller is to stand, for if he has to stand on lumps of coal, etc., he may lose his balance, or he will at least have to exert extra energy to steady himself. Far less energy would really be used in sweeping up the floor occasionally.

Convention Notes

At a luncheon of the Canadian Electrical Association, during their convention held in Montreal, the members were pledged to promote international security between Canada and the United States, and to use the agencies of electricity and electrical research for the mutual benefit and protection of the people of the two countries.

The Summer Convention of the Association of Municipal Electrical Utilities opened at Orchard Point, Orillia, on June 13. The following are the officers of the association: president, A. T. Hicks; vice-president, J. E. B. Phelps; secretary, S. R. A. Clement; treasurer, G. J. Mickler.

At the Ninth National Exposition of Chemical Industries which will be held at the Grand Central Palace, New York, from Sept. 17 to 22, the progressive tendency in the chemical equipment field will be demonstrated.

At the convention of the Electrical Co-operative Association held in Montreal, the following officers were elected: hon. president, Geo. Templeman; president, P. A. McFarlane; vice-president, D. H. Ross; secretary and treasurer, T. H. Chennell.

Martin D. Brayman, an old and trusted employee of the James Smart Mfg. Co., up to the time of its absorption by the Canada Foundries and Forgings, and who continued on with the latter, has been pensioned off by the company after fifty-two years of continuous service. Mr. Brayman is seventy-two years of age.

Electricity in the Power House

MODERN CASCADE MOTORS

WITH the ever-increasing use of alternating current, especially in conjunction with cheap power supplied from hydro-electric plants, the motor user is always ready to welcome any new type or system showing improved operating results.

While the modern alternating current motor leaves little to be desired, the single field cascade type has recently come to the front as a machine specially suitable to certain applications, and is being regarded with favor by many electrical engineers.

The principal feature is, that with the single speed machine there are no slip rings, the motor is capable of exerting twice the full load torque even down to creeping speed without trouble, and any particular machine will stand a momentary overload of 150 per cent.

Comparison of Types

In the old system of cascade operation two distinct machines were used. The stator of the first being connected to the mains and its rotor connected to the stator of the second. When running at cascade speed the second rotor would be short circuited. Alternatively the two rotors were connected and one of the stators short circuited.

While with two separate motors there are two entirely separate magnetic fields, in the single field type having but one core, the two fields, although existing as components, merge into a single resultant field, likewise the two individual stator and rotor windings are replaced by a single winding, that of the rotor being so connected that the currents induced in it produce two magnetic fields in that of the stator so that "main" and "slip frequency" currents can circulate independently.

At the same time the windings are quite simple. Both electrically and magnetically, the single field motor is identical in action wtih a cascade combination of two machines, the combination only affecting the cost, efficiency and power factor, in other words, there is a stator winding connected to a supply which induces in turn currents in the rotor winding.

The production of these two distinct fields is brought about by the manner in which the two coils are arranged. An eight pole element corresponds to the main stator field and a four pole field rotating in the opposite direction induces voltages in the stator winding which is so connected that induced currents can flow independently of the currents supplied from the mains, these currents producing a field corresponding to the four pole rotor field.

The Single Speed Motor

This type of machine is practically a squirrel cage motor, the rotor winding being completely short circuited.

The starting torque and speed are under complete control by regulating resistances connected to the stator tappings. A back E.M.F. is induced in the rotor conductors by the auxiliary rotor field permitting only sufficient current to flow to produce the required torque. This, at starting, can be varied at will by means of the stator tapping resistances. While behaving like a slip ring motor and taking about full load current for full load torque, unlike the slip ring motor, the rotor voltage at standstill is very small and being quite stable at rest, starting is effected without a jerk. This is due to equality of turning moment for different positions of the rotor so that these machines will run steadily when 100 per cent. overloaded and, at only 2 per cent. of normal speed.

In consequence, the single speed cascade motor is entirely suitable for haulage purposes in mines and quarries, for driving rams, pumps and compressors, paper mills, and other machinery in steel works, flour milling machinery, etc., and for several other uses especially in dusty situations.

Resistances Connected

When it is not required to regulate the starting torque, resistances are connected permanently to the stator tappings to give the required starting torque, these being short circuited by a switch when the motor has reached full speed.

By using two separate windings for the stator, the motor may be controlled by a standard three phase controller.

Multi-Speed Motors

In this case slip rings are necessary and these being short circuited in the case of two-speed motors, the currents in each section of the winding are in phase with the corresponding voltages and no secondary field is produced. Thus the motors when so connected run as normal motors at speeds corresponding to the number of poles in the main winding, the second speed being usually two thirds the full speed, with the number of main poles being half that of the auxiliary ones, a ratio of 3 : 1 is obtainable.

The full speed can be arranged to correspond to any number of poles greater than 2.

They may be hand controlled or the speeds changed automatically by means of a contractor gear. The field of application of these multi-speed motors is greater than that of the single-speed, and they are suitable for air compressor work, especially for units installed for a greater capacity than immediate requirements demand, the second speed being brought into use at a later date to meet the increased demand.

Winding Engine Work

Two-speed control with alternating current is analogous to series-parallel control with direct current, but has the added advantage of the main circuit not being open when the connections are changed. A winder is accelerated in two stages which dovetail into one another; at starting the slip ring circuit is open and the controlling resistances are connected to the induction circuit of the stator. The cascade coupling and the winder will accelerate to two-third speed. During the second stage the resistances are connected to the rotor, the second stator winding is opened, and by gradually short circuiting the resistances, the winder runs up to full speed. Preferably the control should be automatic, hand control may suffice for a small machine. For a given kilowatt input, the motor connected in cascade develops approximately 50 per cent. more torque than it does when connected to resistances through the slip rings.

For minimum kilowatt peak, the input is kept constant during both stages of acceleration and as the torque during the first stage is 50 per cent. greater than during the second stage the acceleration is also greater. This is of advantage as it gives a smoother effect.

This increase in the torque per k.w. greatly reduces the input during acceleration and for winders of moderate depths, the peak is 25 to 30 per cent. less than for similar winders driven by straight induction motors. The power consumed per wind is reduced. Generally the cascade connection is only required during accelerating or retarding and in consequence the SR losses in the stator secondary circuit are of little account as they merely form part of the controlling resistance losses. For this reason it is good practice to use two entirely separate windings for the stator, one the main winding of the usual type for connecting to the line; the other similar winding connected for half the number of poles of the main winding with three phase connections for coupling to the controller.

—JOHNSTONE TAYLOR.

Every-day Problems With Answers

Queries are invited on the every-day problems of all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped to solve a problem and a pleasure for us to pass on the data.

PIPE LAYOUT

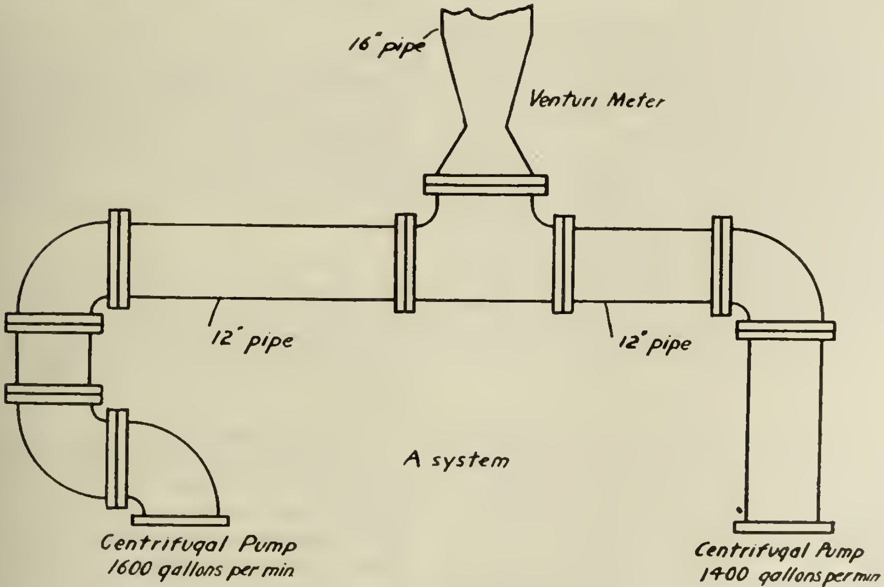
The accompanying sketch (scheme A) shows our present piping system, which has been condemned by several as a serious detriment to maintaining a pressure in the city mains. What would be the actual gain in lbs. per sq. in. by substituting the system shown in scheme B?

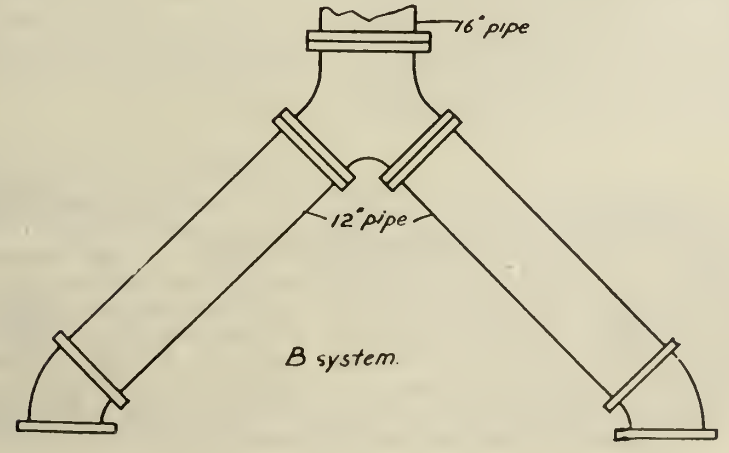
E. MAYHEW

Answer:—It is not possible to give any accurate information as to the actual gain, no lengths of pipe are given, and the condition of piping and elbows is not known. Hydraulically, scheme A is bad, there are too many 90 deg. elbows; and a sharp turn at the T.

With a good Venturi meter the loss in head is scarcely noticeable, but if the meter is located, as in your sketch, it will not give any accurate readings, due to eddies caused by the T. It should be at least 10 pipe diameters from any sharp turns.

With scheme B there certainly would be a gain in head, but it would be small on account of the fairly low velocities in the pipe line (about 4 ft. per sec.). The gain in head using system B might be about one lb. per sq. in.





ALTERNATOR SPEEDS

We have in our plant a Corliss engine driving an alternator. The engine is now running at 150 r.p.m., develops 200 k.v.a., 240 volts, 481 amperes per terminal, three-phase, 60-cycle current. With the engine running at 150 r.p.m. the exciter speed is 1,200 r.p.m.

The engine is capable of running 160 r.p.m. with its present gravity gear.

Would the exciter have any effect on the alternations of the current with quick changes of load?

The exciter should run only 1,100 r.p.m. instead of 1,200 r.p.m. Has this any effect on the alternations?—R. L. BOOTH. Windsor.

Answer:—The cycles in alternating current are dependent on the number of poles and the speed of the machine. As no change in the construction of the machine is to be made, the frequency is directly proportional to speed.

If your machine gives 60-cycle current at 150 r.p.m., with a speed of 160

$$\text{frequency is} \frac{160}{150} \times 60 = 64$$

You cannot change the speed of the engine without a change in the cycles.

The changing of the speed in the exciter would have but small effect on the unit. An increase of speed would give a higher voltage tending to cause over-excitation of the alternator field. Simply put more resistance between the exciter and the alternator.

WARM COOLING WATER

We have a carbon dioxide refrigerating system, but in order to get its rating, must run the compressor at twice its normal speed. The condenser pressure is 1,100 lb. per sq. in., the coil pressure 300 lb. and the cooling-water temperature from 77 to 87 deg. F. on and 110 deg. off. What is wrong?

Answer:—It is necessary to have a temperature drop between the carbon dioxide in the condenser and the cooling water in order to cause the heat to flow from the hot gas to the water. This temperature difference would probably be in the neighborhood of 10 deg. F.—the temperature in the condenser would then be 97 deg. F. This is above the critical temperature for carbon dioxide. By critical temperature is meant the temperature at which carbon dioxide gas will not liquefy into liquid carbon dioxide, no matter how high the pressure is that is placed on the condenser. This critical temperature is in the neighborhood of 86 to 87 deg. F., and if your carbon dioxide gas is at a higher temperature, you will not be able to condense it. Under these circumstances the only thing that goes through the receiver and expansion valve into the evaporating coil is carbon dioxide gas. The cooling effect that you do obtain is due to the temperature drop caused by the expansion of this gas from 1,140 lb. to 300 lb. Incidentally, this is a small percentage of the refrigerating effect that you would be able to obtain if liquid carbon dioxide were passing through the expansion valve and boiling in the evaporating coil.

It is quite possible that you have some liquid carbon dioxide going to the receiver and through the expansion valve to the evaporating coil, for the reason that the gas drops below the critical temperature, and the temperature drop causes some of the gas to condense, say 20 per cent.

The result of the high cooling-water temperature is that your plant capacity is reduced, and to offset this, the compressor speed must be increased to handle a larger volume of gas. The solution is to find a cooler condenser-water supply. You should have it at least below 75 deg.

EFFECT OF ASH

What effect has the presence of different proportions of ash and slate on the value of steaming coal?

Answer:—The efficiency of combustion ordinarily decreases with increase of ash or slate and incombustibles mixed with the coal and there is also the additional expense for storing, handling, firing and ash disposal. High-ash coals require higher draft because the ash forms an insulating layer around the coal, which hinders the oxygen from coming in contact with the combustible material and the ash may clinker and clog the fuel bed so the higher draft required results in more leakage of air through the walls of the setting. Hence, the higher the percentage of incombustible the greater the loss from excess air and the lower the efficiency obtainable for the combustible element in the coal.

The relative value of coals according to the percentage of ash content varies with different boiler plants. Under average plant conditions the relative values are about as follows:

Taking 0 per cent. ash as 100, 10 per cent. ash in dry coal would have a value of 92; 20 per cent. ash a value of 80; 30 per cent. ash a value of 60; 35 per cent. ash a value of 40; and 40 per cent. ash a value of 0.

STARTING A. C. GENERATORS

In synchronizing motors and generators to the station bus, the power factor meters usually indicate a low-lagging power factor. Is this due to improper synchronizing or improper adjustment of the field current? Do the machines keep the phase relations they had at the instant the switch is closed, or is there a slight change afterward?

Answer:—When starting a synchronous motor, it takes a lagging current from the line due to the machine being started as an induction motor, and therefore its magnetization must be supplied from the alternating-current circuit. After the machine has been brought up to speed and the field coils are connected to the direct-current excitation source, the magnetization can be adjusted to bring the power factor to unity, at which value all the excitation is supplied from the direct-current line.

In connecting an alternating-current generator in parallel with other machines, there are a number of combinations of voltage and speed that can be made to exist when the switch is closed on the incoming machine. If the voltage is high on the incoming machine, it will supply a lagging current to the other machines on the system when connected to the busbars.

On the other hand, if the voltage of the incoming machine is low, the other machines will supply a lagging current to it. A little experimenting should show the best voltage at which to connect the machines to the bus. It is generally best to close the switch with the incoming machine running a little fast and the voltage a little high. Then the machine will pick up some load from the system when the switch is closed and tend to relieve any disturbance that might be caused in the paralleling operation. After the switch is closed, all machines must take the same phase relation and continue to retain this condition. If they all have the same number of poles, they will run at the same speed. The only difference will be in the angular position of the rotors corresponding to the proportion of the load each machine may be carrying.

GETTING UP STEAM

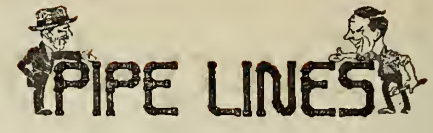
Having the manhole and handhole plate removed, how would you proceed to get up steam?

Answer:—After thoroughly cleaning and examining all parts of the boiler, stays, fusible plug, seams, etc., and finding them in good condition, replace the lower plates with good gaskets, then close the blowoff valves, and fill the boiler with water, comparing the water level with the gauge cocks or glass. Being satisfied, replace the top plate using a new gasket if necessary, and after examining the feed appliances and finding them in good working condition, proceed to light the fire, allowing the steam pressure to build up very slowly. It may be necessary to open a vent.

To reverse the direction of rotation of a series motor either reverse the series field connection, reverse the armature leads, or shift the brushes backward, as explained for the shunt motor.

Heating is manifest soonest, with the same expenditure of energy, in small bodies because they are not capable of absorbing the heat generated, therefore feel hot to the touch, while the same energy expended on large masses will produce only a slight rise in their temperature.

If a 60-cycle transformer is to be operated on a 25-cycle circuit, the voltage should be reduced to about one-half that rated and the capacity will be correspondingly reduced; otherwise excessive heating will result with continuous operation. Conversely, a 25-cycle transformer may be operated on a 60-cycle system with double the voltage at which it is rated for 25 cycles, providing the insulation will safely withstand the current.



UNCOVERED IN ANY OLD SPOT

A fireman from Woodstock was so ignorant he thought that stick candy was made from kindling wood.

* * * *

Terminal pressure is the pressure that would be in the cylinder at the end of the stroke of the piston if the exhaust valve did not open until the stroke was completed. On a steam-engine-indicator diagram the terminal pressure may be found by extending the expansion curve to the end of the diagram. The theoretical terminal pressure is found by dividing the pressure at cut-off by the ratio of expansion.

An engineer who lived in Montreal,
Fell into a spring last Fall.
Had he fell in this Spring,
'Twould have been a sad thing,
But he didn't, he fell in the Fall.

* * * *

To distinguish between a parallel and a series-connected armature winding first note the center of the coils at the back of the armature. If the leads to the commutator are in the same direction as the back ends of the coil, that is, if they swing in toward the center, the winding is parallel connected. If the leads swing around the armature, away from the center of the coil, the winding is series-connected.

If nothing appears in this column in the next issue of Power House you'll know somebody laid off to telephone.

Tallow oil, when derived from fresh tallow from properly fed animals, is a good lubricant, but lends itself readily to adulteration and may become rancid and acid. It forms the base of the best white soap, and, if a large enough percentage of soap is added to the oil, it becomes a grease.

Practical Ideas From Practical Men

HERE is an argument tending to prove that the smooth or hair side of a belt should be run in contact with only one pulley of a given drive, and the rough or flesh side of the same belt should come in contact with the other pulley. By so doing creep will always be in the same direction, the projecting fibres will always be smoothed down in the same direction, and as a result there should be less wear. To do this belts cannot be operated in the usual fashion. A "twist" must be made in the belt as indicated in Fig. 2.

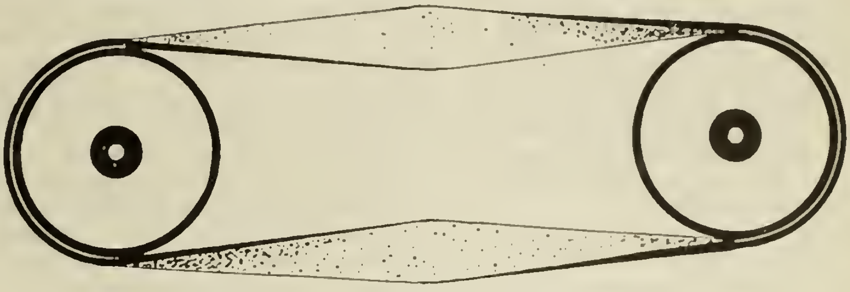

FIG II

Belt manufacturers and users will agree that a piece of leather or other fibrous material can be worn down more quickly by rubbing "back and forth" than by constantly rubbing in the same direction. When a carpenter sandpapers a piece of wood, he rubs the paper "back and forth" over the wood in every direction because he finds the wood will smooth down better and more quickly in that way. Pull a sack of rags, say, over a patch of grass constantly in the same direction and count the number of passes necessary to wear off the grass. Then repeat the experiment on a similar patch of grass except that the dragging will be "back and forth" over the same path. Doesn't it stand to reason that the grass in the second experiment will be "irritated" more and will wear off sooner?

Belts as ordinarily placed on pulleys are subject to this "back and forth" rubbing due to the fact that all belts creep. The writer has never seen this point covered in print, and since there are many thousands of belts in daily use all over the country it is a matter that seems well worth discussing. If the life of a belt can be lengthened by giving the belt a twist as indicated in Fig. 2, and for the reasons given above, the belt should by all means be twisted if the conditions of the drive are such that it can be done without impairing transmission.

Fig. 1 shows a belt with the projecting fibres exaggerated. Space is left between the pulleys and the belt for the purpose of showing distinctly how the fibres behave when coming into and out of contact with the pulleys and while in actual contact. Belts always creep toward the tight side. They must creep that way. There is nothing else for them to do so long as they possess elasticity. All belts, even steel, are elastic. That being the case, let us trace the action of the projecting fibres of the belt in Fig. 1. As the belt comes into contact with the driver pulley shown at the left the fibres are leaning over toward the right, because that is the way they were "rubbed" by the driven pulley which they just left. Immediately upon touching the driver pulley, though, the fibres find that the belt is creeping towards the tight side in opposition to the direction of rotation of the driver pulley. At the point marked "A" therefore, a turning point occurs and soon thereafter the fibres are smoothed over in a direction opposite to that in which they approach the driver pulley.

The fibres now rush over to the driven pulley with an antagonistic slope as shown on the top side of the drive. Upon touching the driven pulley, though, these fibres find that the belt is traveling faster than the driven pulley because creep is again toward the tight side and at the point marked "B" we have another turning point where the fibres are combed, bent or rubbed back to the original position. Then the fibres dash over to the driver pulley once more and they are again reversed. And so on.

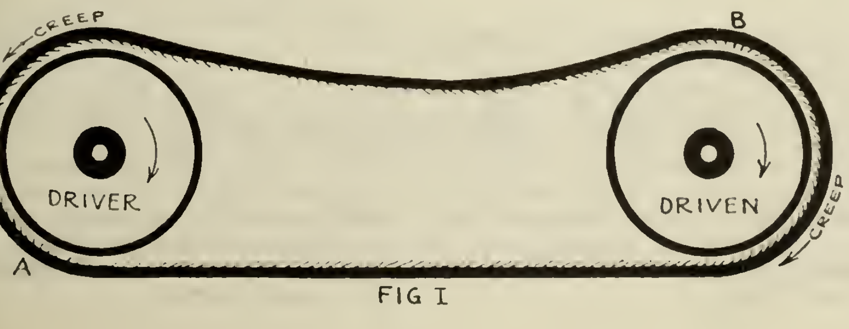

FIG I

Every time a projecting fibre comes in contact with a pulley in drives of this kind it is reversed in direction. This occurs revolution after revolution, day after day, year after year, and there is, therefore, little wonder that unless a belt is properly cared for it will wear out quickly.

No doubt there are ways in which this wear can be largely prevented. It is evident that if the belt is "bone dry" the wear is bound to be more rapid than if it is lubricated, for the same reason that metallic rubbing surfaces must be lubricated if wear is to be reduced to the minimum. Lubricant fills up the "rough spots" in the metal, thus allowing the "bumps" to pass over one another.

In the case of a lubricated belt the action may be somewhat different. The lubricant will probably not fill up the entire space sufficiently to prevent the projecting fibres from coming in contact with the pulleys, but the fibres will be so well lubricated that they will bend back and forth more easily and without appreciable or serious wear.

No doubt there are several solutions to this problem. For mechanical reasons it is often undesirable to give such a twist to a belt as shown in Fig. 11. Perhaps it can be avoided by applying a wearing face to the belt and operating in the usual way. The writer, however, does not know of any practical wearing face aside from sticky preparations, and they often do more harm than good along the line of excessive power consumption. It may be, also, that the reversal of direction of projecting fibres has much to do with the pulling power of a belt. In the opinion of the writer a greater pulling power can be obtained with a belt in which the fibres do not reverse, because contact can be made more intimate. That, however, must be left to experiments and experience, on which reports may be made later. The subject has at least been broached, and is left with the reader to do with it and think of it as he will.

COVERING PIPES

Faced as we are at present with the scarcity of coal and the need for conserving the supply as much as possible, the following comments may not be out of place.

It is not uncommon at the present time to go through a power plant and see various steam lines uncovered or only partially covered, the owner or manager of the plant apparently not having considered the loss he was incurring through the extra fuel required to make good the radiation losses of uncovered pipe lines. The following example will give an idea of the radiation of an uncovered pipe:

Example: Required the radiation per annum from a steam line 100 ft. long by 10 inches diameter, steam pressure 150 lbs. per sq. in. Average air temperature 76°F. Plant to operate ten hours per day, three hundred days per year. The temperature of steam at 150 lbs. pressure is 366°F. The difference in temperature between the steam and air = 366 - 76 = 290°F. Loss of heat per sq. ft. pipe surface per hour per degree difference in temperature = 3 B.T.U., approximately.

Then loss of heat per sq. ft. per hour = 3 x 290 = 870 B.T.U. Then loss of heat per sq. ft. per day = 870 x 10 = 8,700 B.T.U. Then loss of heat per sq. ft. per year = 8,700 x 300 = 2,610,000 B.T.U. 100 lineal feet of 10-in. pipe has an external area of 282 sq. ft. Therefore the loss per year from bare pipe is 2,610,000 x 282 = 736,020,000 B.T.U., approximately.

Assuming a net available heat value of coal at 10,000 B.T.U. per lb. for coal, the equivalent coal consumption is

$$\frac{736{,}020{,}000}{10{,}000} = 36.5 \text{ tons.}$$

For example take coal at $10 per ton. Then value coal lost in radiation: 36.5 x $10 00 equals $365.00.

Good pipe covering will save from 70 to 80 per cent. of this loss. Therefore saving per annum would be:

$$\frac{70}{100} \times 365 = \$255.50$$

Comparing this saving with the cost of 100 ft. of 10-in. pipe covering it should not take long to pay for the pipe covering.—M. C. ALLIN, 839 Lorne Ave., London, Ont.

FIGURING DENSITY

The density of an oil or other liquid can be determined with accuracy without the use of a hydrometer. If you have an accurate weighing instrument you can do a more accurate job in fact than with hydrometer.

In a nutshell, this is the method:—

(a) weigh a clean empty jug.

(b) weigh again when filled with water.

(c) weigh again when filled with oil.

The density can then be determined by using this simple formula:—

$$\text{Density} = \frac{c - a}{b - a}$$

This, you will note, is nothing more or less than dividing the weight of a certain volume of the oil by the weight of the same volume of water. If you have accurate and delicate weighing balances I would suggest that you use a small vial for this test. If you have nothing but large scales for weighing heavy objects, you can do the test very well by using a large or ordinary jug as suggested above. The temperature of the water, oil and jug should all be the same while doing the test. If possible, the temperature of all three should be 60 deg. F., as that is the standard.

Trade Catalogs

The B. F. Sturtevant Company, of Boston, Mass., in Catalog 311 emphasize the fact that their Type 12 Steam Turbine retains all the fundamentals of previous types and, in addition, embodies numerous refinements in detail construction. One of the principal and most advantageous changes made, it is claimed, has been the splitting of the castings on the horizontal center line. This allows the turbine to be entirely disassembled without disturbing the setting on the foundation in any way, besides allowing ready accessibility to the rator and nozzle segments for inspection purposes.

A complete and well-written fifty-six page bulletin has just been issued by the Sturtevant Company of Hyde Park, Boston, Mass., on the Type 12 Steam Turbine.

Part one gives in detail the construction of the various parts, profusely illustrated by photographs; it also suggests applications where such turbines can be used.

Part two is on the care and operation of the turbines, embracing such paragraphs as lubrication, bearings, adjustments, and points to remember. In this part also, dimensions are given.

Part three shows disassembled views and cross-sections with every part properly listed and numbered.

A copy of this bulletin, No. 311, will be gladly forwarded on request.

Double Suction Volute Centrifugal Pumps.—This is a new publication, No. 7350-C, 16 pp., 8½ x 11, issued by the Canadian Ingersoll-Rand Co., Limited, Montreal. It is well illustrated and clearly written, containing much interesting information on the special features of these pumps, methods of testing, etc., and will be gladly sent on request to any interested reader of Power House.

Construction

At a meeting of the Northern Mexico Power & Development Co., Ltd., held in Toronto in June 26, the following directors were elected: president, W. D. Ross; vice-president, Strachan Johnston; secretary-treasurer, W. L. Reed.

The Hydro-Electric Power Commission, North Bay, Ont., incurred a loss of approximately $100,000 when the sub-station on Harriet St. was completely destroyed during an electric storm, July 3.

The W. H. Yates Construction Co., Hamilton, have been awarded the contract for the construction of a $200,000 unit addition to the plant of the Canadian Westinghouse Co., Hamilton.

J. H. Black, of the Northern Canada Power Co., reports that work on the power development at Des Quinze is being rushed. The power plant at Lower Sturgeon will be in operation this month.

Hollinger Consolidated Gold Mines, Ltd., 85 Bay St., Toronto, are carrying on the construction of a power plant on the Abitibi River at Island Portage, in an aggressive manner in order to secure the benefits of the development at the earliest possible moment.

D. Woolsey, of Revelstoke, B. C., recently sent to the B. C. Chamber of Mines what is regarded as the best specimen of asbestos yet received. The possibility of making British Columbia independent of Quebec as regards the supply of asbestos is now being discussed by B. C. mining men.

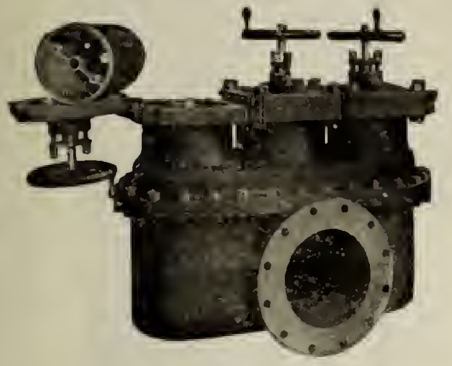
D. C. Coleman, vice-president of Western lines of the Canadian Pacific Railway, states that traffic demands and financial conditions will determine when the actual work of electrifying sections of the road through the Rockies will be commenced.

Edward McGivern, Victoria, B.C., master mechanic of P. Lyall & Sons Construction Co., Ltd., has invented a device which when attached to the carburetor of an automobile, acts as a fuel saver, giving the motor considerably more power, and practically eliminates carbon. This device has been thoroughly tested, and in two tests thirty miles to the gallon have been made.

John P. Forde, district engineer of the Public Works Department, Esquimalt, B.C., who is supervising the construction of the drydock there, states that all the mechanical equipment, which will include main, auxiliary, fire pumps, valves, sluice gates, machine shop equipment, capstans, caissons, traveling-cranes, etc., will be electrically operated arrangements having been made with the B. C. Electric Co. for the supply of the necessary power.

We Supply
Automatic Water Softeners

For the purpose of removing by chemical means the scale-forming matter from water.

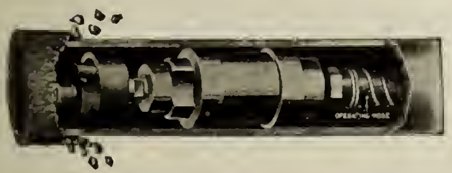


Three Basket Filter

These filters have from one to six baskets and can be arranged to remove foreign matter to any degree of fineness.

Lagonda Water Driven Cleaner for Curved Tubes

Lagonda Air Driven Cleaner for Straight Water Tubes



Cleaner Removing Scale from Outside of Fire Tube

ALL natural waters contain some impurities, which, when introduced into a boiler, may appear as solids deposited on the heating surface. No matter what the substance consists of, it must be removed at frequent intervals or it will decrease the capacity and efficiency of the boiler and may cause it to be badly damaged by over-heating.

Some waters, notably well waters, deposit such quantities of scale that it should be purified before going into the boiler, thereby preventing an accumulation of incrustation and consequent damage to boiler parts, and at the same time effecting a large saving in fuel by keeping all parts of the heating surface in a clean and efficient condition. If you have bad feed water it is a case for the chemist, for the scale is probably composed of several substances which must be known before the exact treatments necessary to get rid of them can be determined upon. The use of treatment without technical advice is poor policy.

Stony and vegetable matter in suspension can be removed by FILTERS, which we supply in various sizes and designs to suit all requirements. In most Canadian plants, lake or river water is used for feed, and these waters seldom carry large quantities of scale-forming materials in solution. Scale can be allowed to form in the boiler for a considerable period. Experience in each individual plant determines the limit at which tube difficulties will begin or a perceptible falling off in efficiency will take place. With such a limit of scale formation fixed, and the danger of allowing it to be exceeded, well understood, probably the most economical and efficient method of keeping the heating surfaces clean is by the use of the LAGONDA TUBE CLEANERS.

The cleaners are designed and so constructed as to thoroughly remove all the scale, in the shortest possible time, at the lowest cost of operation, and they require a minimum amount of repairs, reducing both the waste boiler time and labor cost of cleaning.

They are made to operate by either water, air or steam, and electricity. In every case a swing head is furnished so designed that three sets of cutters are thrown out by centrifugal force against the scale in such a manner that they make straight line contact with the tube and they do the work without damage to it.

You can be supplied with LAGONDA tools for cleaning Economizers, Condensers, Evaporators and other tubular plant.

Catalog and full particulars for the asking.

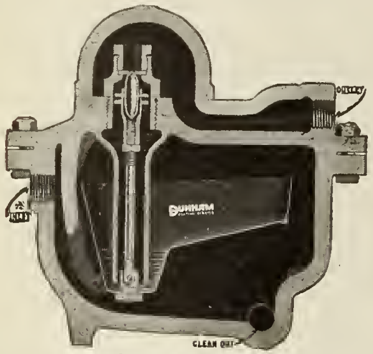
Progress in New Power Equipment

A BUCKET TRAP

The Dunham type No. 80 bucket trap for high pressure service which the C. A. Dunham Co. have recently placed on the market, attracted considerable attention at the C. A. S. E. convention at Toronto. This company specializes in the manufacture of heating and power plant specialties and produces a line of steam traps to meet a wide range of uses.

The manufacturers claim that a new and distinctive feature is incorporated in this new bucket trap—namely a quick, snappy, closing action.

It is quite fully appreciated that bucket traps generally are slow or draggy in their closing action, and this condition causes more or less wire-drawing and cutting of valves and seats, with incidental maintenance expense, and loss of steam.



Dunham Steam Trap.

The Dunham bucket trap operates on the same principle as other bucket traps, but the destructive effect of steam wire drawing the seat is reduced to a minimum, by the quick closing accomplished through the shape of the Dunham bucket. The proportion and shape of the bucket is such that when it begins to rise, all water inside the bucket is shifted towards the hinge, filling the water seal and the movement of the bucket upwards is accelerated, which produces a quick, positive, forceful action and reduces the wear on the valve and seat.

The C. A. Dunham Co., Ltd. have recently issued a new bulletin on this line, completely describing the product. Every steam plant engineer can procure a copy of it by writing the manufacturers.

NEW TYPE OF FURNACE

The Gates Engineering Co., Ltd., 314 Notre Dame St. West, Montreal, is one of the firms who specialize in boiler setting and furnace building, oven work and power plant brick work.

J. W. Gates has had a wide experience in this field of operation. He has United States and Canadian patents covering furnace linings, non-clinking furnace blocks, arches and jambs, air cooled and water cooled suspension harness for flat arches suitable for burning sawdust, shingle hairs, edgings, tan bark, paper mill refuse, etc.

To burn these waste fuels under boilers efficiently depends upon three conditions—high temperature, correct supply of air, complete mixture of preheated air with fuel gases and taking care of 50 per cent. moisture.

In a new type of furnace installed in a large pulp and paper mill, Mr. Gates claims to have provided a perfect method of feeding the fuel to the grates of the furnace at precisely the rate at which combustion takes place. The furnace, which is fitted with grates at an angle of 54 deg., permits the fuel to flow in a flat stream covering the grates with an even bed. As the fuel is consumed more is supplied by gravity and a bed of unvarying thickness is maintained. The thickness can be changed at will to suit the draft by raising or lowering the fuel louvers. The flat fuel bed of sawdust insures proper draft distribution and greatly increases the rate of combustion. With the furnace just installed the company are developing, it is claimed, 747 h.p. with a water tube boiler containing 5,000 square feet of heating surface.

A set of shaking and dumping grates is fitted to this type of furnace and also a moisture absorbing roof.

A DEEP WELL PUMP

A new type of deep-well pump has been developed by the Worthington Pump & Machinery Corporation, represented in Canada by the Storey Pump & Equipment Co., Excelsior Life Bldg., Toronto, operating on a principle heretofore not used in pumps of this kind. Although the pump is of the rotary class the water is not elevated by means of a conventional type of impeller, but a form of propeller is used similar to that employed for propelling ships.

The most radical departure in this pump, which will interest present and future users of deep well pumps, is shown in Fig.1. This is a section through a well casing and drop pipe. It illustrates one set of discharge vanes, the impeller, the shaft, the shaft coupling, and the bearing.

Fig. 2 shows the general arrangement of this pump as applied to deep wells with a direct connected standard vertical motor drive on the head. As will be noticed with this arrangement there is no conversion from horizontal drive to vertical drive. There are no right angled drives at all. Everything is in a perfectly straight line.

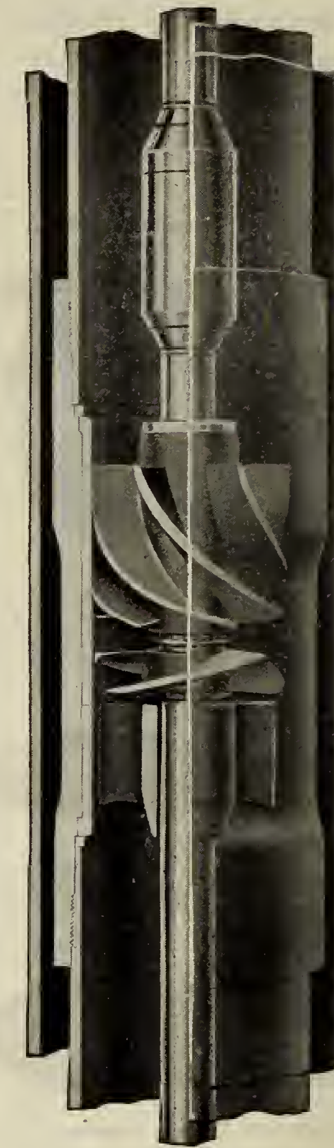


Fig. 1.

In comparatively shallow wells one set of impellers might suffice, but in very deep wells a number of impellers are necessary, these being placed one under the other, thereby making the pump equivalent to a two-stage, three-stage, or other multi-stage pump.

Where it is desired or necessary to operate this pump by means of a horizontal motor, steam engine, internal combustion engine, or by other means through a horizontal drive, a vertical pulley for belt driving may be placed on the head as shown in Fig. 3.

Where water must be elevated to a considerable height above the ground level a centrifugal "booster pump" is added and connected to the pump shaft at the ground level. This combination

Highest Efficiency in 1943

Asbesto-Sponge Felted Insulation

THE FACT that Asbesto-Sponge Felted Insulation is the most efficient insulation on the market to-day is important—but more important is the fact that after twenty years in your plant it will still retain its efficiency.

The construction of Asbesto-Sponge Felted is durable as well as efficient. It will not pulverize under vibration. It will not break or crack under shock. You can hit its laminated structure with a hammer and it will not crack or crumble. It lasts indefinitely—and without deterioration.

Here, then, is an insulation that will appeal to every far-sighted engineer — an insulation with greater ability to save heat, and greater endurance to keep on saving heat. Johns-Manville Asbesto-Sponge Felted Insulation combines maximum efficiency with maximum strength for maximum economy.

Many tests have conclusively proven the laminated construction of Asbesto-Sponge Felted Insulation the most efficient on the market.

You can hit Asbesto-Sponge Felted Insulation with a hammer — one of many tests that prove its durability.

gives one compact unit the same as would be ordinarily obtained by using two different pumps, one for deep well pumping and the other for above surface elevating. Fig. 4 shows this booster pump at the bottom with the discharge pipe emerging at the left. At the top is a standard vertical motor. Midway between the top and bottom is shown the housing for the thrust bearing.

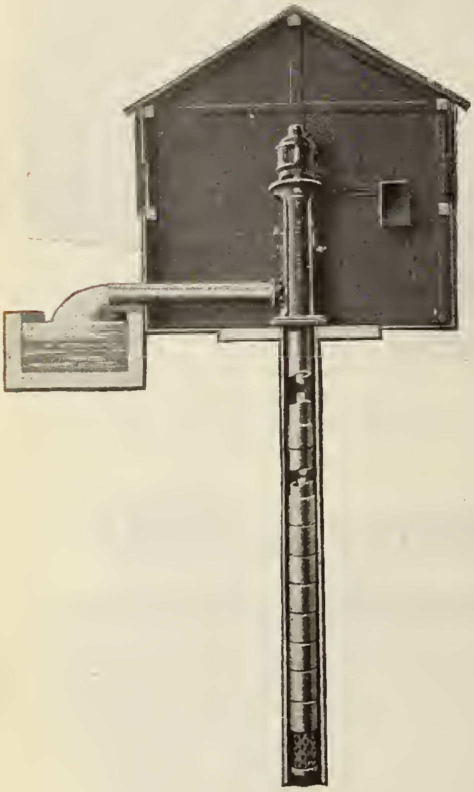

Fig. 2.

The impellers are made of hard bronze capable of withstanding the corrosive action of the usual well water. The number of, and angle of, impeller blades, together with their width and thickness vary with the conditions and are based upon calculations and tests which indicate the proper proportions for capacity and efficiency. The discharge vanes, clearly shown above the impeller in Fig. 1, receive water from the impeller and convert the velocity of flow into pressure and at the same time cause the water to flow upward smoothly along the axis of the pump. These vanes eliminate eddy currents and their accompanying waste. The shaft is of nickel steel and is divided into easily handled lengths, coupled together by long steel coupling insuring good alignment.

If your capacity to acquire has outstripped your capacity to enjoy, you are on the way to the scrap-heap.—Glen Buck.

The weight of the moving parts and the water column thrust are taken up in a specially designed three-plate self-adjusting type bearing. The top or plate thrust rotor is an iron plate which rotates with the shaft. In the center is a babbitt-faced bearing plate, the upper face of which is scraped to a true bearing surface with the top plate. The bottom plate or thrust washer supports the middle plate on a ball-and-socket seat.

The entire bearing runs submerged in oil, and holes through the center plate allow the lubricant to pass to the cavity inside the plates where it is picked up by the top plate and distributed through an oil groove arrangement to the bearing surfaces, between the top and middle plate. The oil bath is waterjacketed, a constant circulation of water being supplied by a small impeller attached to the pump shaft. The piping for water circulation is visible in Fig. 4. The self-aligning feature of this bearing and the fact that it runs submerged in a bath of water-cooled oil materially reduces the attention required by the thrust bearing. In fact, the only requirement here is the periodic filling of the thrust casing with oil.

The smooth operation of the pump, the uniform flow of water and the absence of sudden strains upon the driving parts insure a long life of economical pumping service.

There is no "royal road" to success. There is no way of paying debts, of receiving benefits, of acquiring property, of securing and retaining positions of employment or office, public or private, or obtaining assistants or workmen, skilled or unskilled, except on the basis of reciprocity, of returning fair equivalent to be mutually agreed upon. Every man or nation in order to measure up to obligations must work, and save; must be prudent and fair and economical.—Judge Gary.

AN OIL ENGINE

It is assumed by most engineers that the solid-injection oil engine cannot be successful when built in small sizes, consequently it is seldom that machines of this type are under 10 horsepower.

The Galt Motor Co., Galt, Ontario, has brought out a small engine that disproves this idea. The machine is of the two-stroke-cycle type with a compression pressure of 350 lb. The crankcase is used as the scavenging pump, delivering air at 15 lb. pressure to the working cylinder.

When direct connected to a 2-kw. 110-volt generator, the engine operates satisfactorily over a speed range from 100 to 1,500 r.p.m. At 700 r.p.m., the standard generator speed, the unit delivered 6 kw.-hr. per gal. of fuel oil.

The fuel is injected into the combustion chamber through a single nozzle, the fuel-pump timing being such that injection starts 5 deg. ahead of dead center and at full load the injection ends at 20 deg. past dead center.

Canadian Exhibition Train for France

Arrangements Now Completed—Formal Opening Fixed for July 15 at Le Havre—French Government Has Constructed Thirty Special Motor Trucks—Two Months to be Spent in Paris

ARRANGEMENTS with regard to the various exhibits of Canadian manufacturers and producers, which will compose the Canadian Exhibition Train for France, are now completed and the formal opening is fixed for July 15,, at Le Havre.

The French exhibition train in Canada was of the usual railroad type, but owing to the unsuitability of French railway trains and stations the French government have had constructed forty large motor trucks, thirty of which will contain exhibition cases approximately 19 ft. 6 in. by 6 ft. 6 in. by 6 ft. 6 in. These cases will be decorated as first-class modern show windows, and the manufactured products and produce of Canadian farms, mines, fisheries, forests, and factories will be attractively arranged within. Ten motor trucks will accompany the convoy to carry all necessary equipment in the matter of lighting, extra supplies, printed matter and baggage.

At each point in the itinerary the thirty exhibition trucks will be drawn up in a double line from twenty to thirty feet apart. The inner sides of the motor trucks will open outwards. The upper leaf will be raised to extend outward as a partial shelter; the lower leaf will be lowered to cover the wheels. The upper leafs will be joined by a vellum covering so that a covered passage-way will protect visitors from inclement weather.

Canadian manufacturers and producers who are represented on the train will benefit both by orders which they may book, and by the opportunity afforded them of establishing agencies or appointing representatives throughout France. A further point which may be of even greater advantage to them is the fact that they will be brought into close contact with buyers and will be able to gather information as to their real requirements as regards quality and style of manufactured goods which will enable them to sell successfully in French markets. No samples or goods of any kind are, however, to be supplied from the train, the entire furnishings of which have been admitted into France through courtesy without a tariff charge.

In co-operation with the French Committee the Government have made arrangements to supply representatives with a list of possible clients at every point visited. Provision has been made by the French Government for the transport and lodging while travelling of 40 persons with the convoy.

The Canadian Government are preparing an attractively designed poster, and have made arrangements to have it placarded in the chief towns and cities of France during the tour of the Exhibition train.

At the completion of the tour the motor convoy will proceed to Paris and will be set up close to the Orangerie near the Place de la Concorde. New features will be installed from time to time to keep up the public interest. The exhibition in Paris will continue for two months.

The MacLean Publishing Company's exhibit of which an illustration is given on this page will take up one end of one of the motor trucks. The exhibit is made to imitate a store window and will display copies of the various MacLean Company's publications. Accompanying the exhibit there will be an attendant who will have a bound file of the latest copies. Specially printed cards in French will also be distributed to inquiring individuals. The attendant has also been supplied with a bound and indexed folder which enables him to give full information in regard to every MacLean publication.

A complete list of exhibitors will be published in a future issue.

Diamond "VALV-IN-HEAD"

As with previous mechanical soot blowers, the use of the Diamond "Valv-in-Head" effects a saving of 4 to 8 per cent. fuel and increases overall boiler efficiency.

As compared to previous mechanical soot blowers the Diamond "Valv-in-Head" also possesses the following distinct advantages:

1. LABOR FOR OPERATION—A saving of approximately 50 per cent.
2. STEAM FOR OPERATION—A saving of 50 to 60 per cent. or more.
3. PIPE, VALVES and FITTINGS—A saving of 50 to 66 per cent. in cost of pipe, valves and fittings.
4. MAINTENANCE—A reduction in annual charges of 25 to 50 per cent. or more. Practically complete elimination of condensate obtained.
5. EFFICIENCY—Greater cleanliness of boiler assured.

One of the most interesting publications in the power plant field is yours for the asking. It describes the savings effected by Diamond "Valv-in-Head" soot blowers in detail.

Ask for your copy of Bulletin 287.

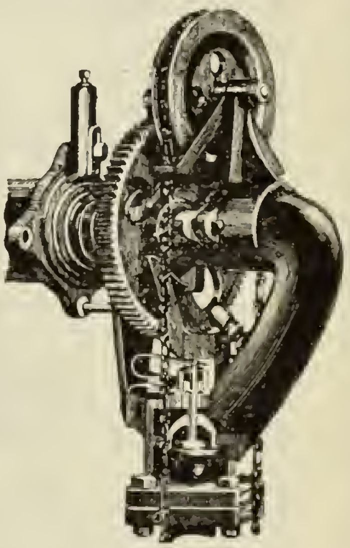
Soot Blowers - Save 4 to 8% Fuel



United Illuminating Co. Bridgeport, Uses Diamond "VALV-IN-HEAD"

GATES ENGINEERING CO., LIMITED

314 Notre Dame St. West, MONTREAL **'Phone Main 662**

Products:

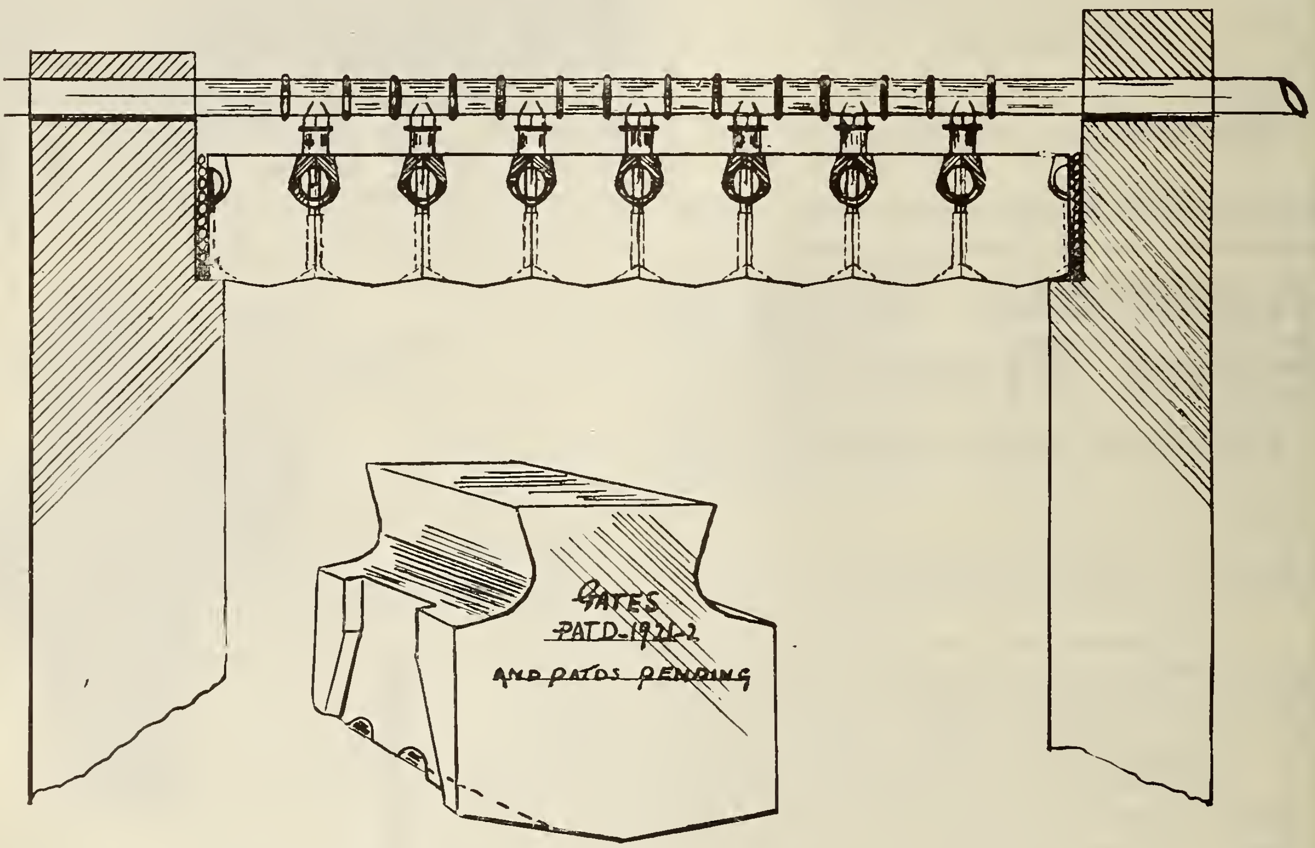
Air-Cooled Refractories
Air-Cooled Suspended Arch

We specialize in Boiler Settings and Furnace Design. Our Engineering Dept. has made a study of Combustion and are in a position to study your requirements, both from an economical and an efficient standpoint, thus enabling you to secure the right setting and furnace design.

Nothing Too Small **Nothing Too Large**

To Economize, call—

GATES ENGINEERING CO., LIMITED



The above cut shows the Gates Patent Air Cooled Suspended Arch. The face of each block is cooled by a current of air passing through slots and distributed over the face of the block thus keeping the refractory below its softening point. Air is also circulated through the harness which consists of 3″ extra heavy pipe, this air being discharged over the fuel bed in the distillation zone at a suitable pressure, velocity, temperature, and volume, thereby aiding combustion, and lengthening the life of the refractory. The construction of the arch is very simple, each block is designed to fit to the pipe and is held in position by retaining wedges, each block is supported independently, allowing any one block to be removed without disturbing any other portion of the arch.

Gates Engineering Co., Limited

Boiler Furnace Refractories

We beg to announce to our customers and others whom it
may concern that

We have purchased from

Gates Refractories, Limited

All their Patents

Covering New and Useful Improvements for Use in

Boiler Settings and Linings

Flat Suspended Arches

Door Arches and Jambs

Under these patents we control the right to sell and install the "Gates Patented" Boiler Arches and Furnace Linings, and these cannot be furnished by any other contractor or supplier without infringing on our patents and patent rights.

GATES ENGINEERING CO., LIMITED

When Does a Paper Really "Reach" You?

1.

Advertisers of the present day are continually having impressed upon them the large number of readers "reached" by this or that medium.

Altogether too much stress is laid upon the number reached; insufficient importance is attached to the manner of reaching them.

As you pass along the street a handbill is thrust upon you. You take it, glance at it, and in all probability immediately throw it away. That advertisement has undoubtedly reached you, but has it reached you in the manner in which you would like your own advertisement to reach the customers you are aiming to get?

It is this question of how people are reached that is really the important one for the advertiser to consider. It is useless "reaching" a large number if you reach them at an unsuitable time and under conditions in which your advertisement will have no effect; everything depends upon the nature of the contact. If this were not so you might as well save the expense of sending out salesmen and send out messenger boys instead. They would "reach" your clients. But you send out a salesman because a salesman is something more than mere flesh and blood. He can do your work more effectively than the messenger boy.

In the same way a publication is more than mere paper and ink. If it is the right kind of publication it is just as far ahead of the handbill or other unsuitable medium for carrying your message as the salesman is ahead of the messenger boy. It will do your work far more effectively.

This is the first of three talks designed to show you how you can satisfy yourself that the medium you choose can not only reach, but reach effectively, and under the most favorable conditions, the man whom you wish to secure as a client.

Look out for No. 2 in our next issue.

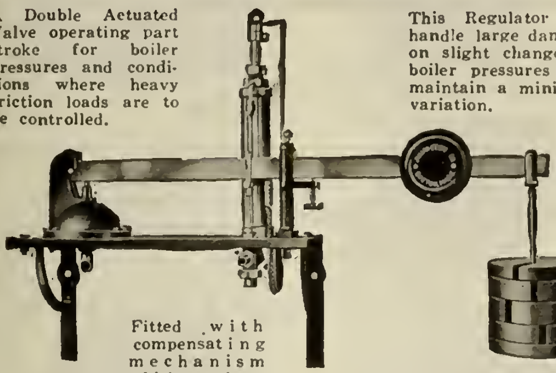
D'ESTE

Hydraulic Damper Regulator

A Double Actuated Valve operating part stroke for boiler pressures and conditions where heavy friction loads are to be controlled.

This Regulator will handle large dampers on slight changes in boiler pressures and maintain a minimum variation.



Fitted with compensating mechanism which regulates opening and closing.

Our Catalogue No. 50 of CURTIS ENGINEERING SPECIALTIES sent on application.

Julian d'Este Company
Main Office: 26 Canal St., Boston 14, Mass.

"SAFETY"

Plastic Metallic Packing

For steam, water, air, gas, etc., is practically indestructible and may be used over and over again. It is

Packing in Cotton Tubes.

GUARANTEED TO LAST THREE YEARS WITHOUT RENEWAL

Packing in Bulk.

It is made of an alloy of the finest anti-friction metals, just hard enough for long service but not hard enough to damage any rod.

The metal is combined with the best lubricating material, making it practically SELF-LUBRICATING AND FRICTIONLESS.

Send for full particulars also about our "Safety" Superheat Sheet Packing.

STEEL MILL PACKING Company

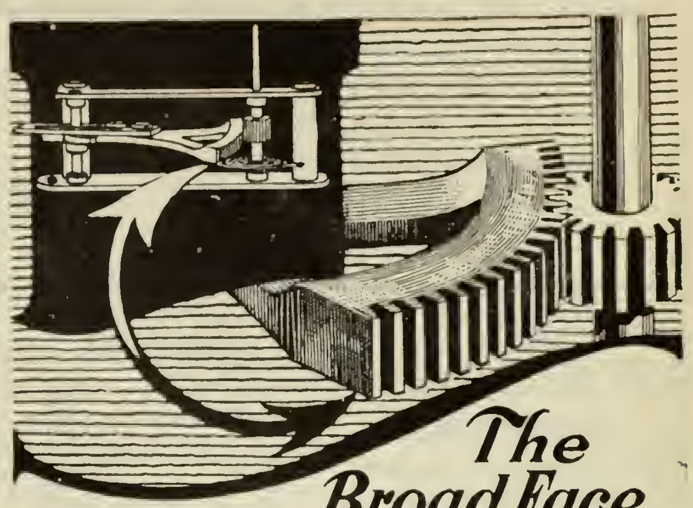
AGENTS WANTED.



The Broad Face gives ENDURANCE

Gears that do heavy work must be broad-faced in order to stand the wear-and-tear.

Note the unusually broad face of the segment illustrated above, and the corresponding broad face of the pinion. The wide working surfaces of these two units reduce wear on the teeth to a minimum in

S&B American

GAUGES

The segment itself is made of specially hard cast bronze, while the shafts and bushings of both segment and pinion are made of the same wear-defying metal. Both segment and pinion shafts also rest in phosphor bronze bushings to further reduce wear.

All the way through, these gauges are built to withstand the most exacting service.

The ability of an S & B American Gauge to resist wear means not only long life—it means that, between segment and pinion, there is a minimum of "play" or "lost motion," which is another way of saying that these accurately constructed gauges RETAIN THEIR ACCURACY long after ordinary gauges are worn out.

Another thing that insures ACCURACY is that each dial is hand-calibrated—each one designed particularly for the gauge on which it is applied.

For dependability and economy S & B American Gauges are in a class by themselves.

Our Gauge Catalog A-33 tells the story in convincing detail. May we send you a copy?

A COMPLETE SERVICE IN

"John Crane"

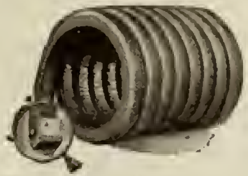
FLEXIBLE METALLIC PACKING

"MADE IN CANADA"

Style 100: Babbitt foil, impregnated with purest graphite and wrapped spirally. Flexible, uniform, compressible.

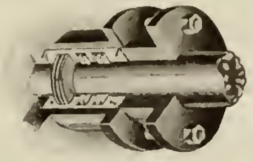
Style 104: Special Ammonia Sets: Alternate rings Styles 100 and 400. Speeds to 450 f.p.m.

Style 601: Condenser tube packing. Patented. Keeps condensers tight. Will not crush or deform tubes.



Style 300: Asbestos channel. Flexible metallic wearing face. For steam, air, gas under high pressures.

Style 400: Duck channel. Flexible metallic wearing face. For plunger pumps, etc., hot and cold water.



Style 801: Floating type inside split case. For use on rising and falling rods. Max. steam pressure 200 lbs.

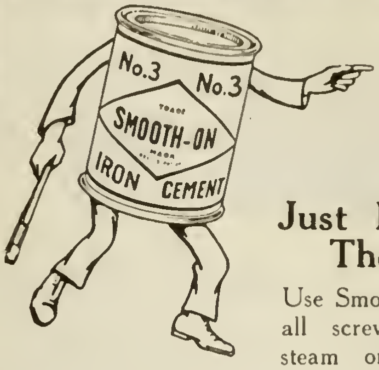
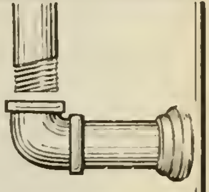
Make tight screw-thread joints with

SMOOTH-ON "No. 3"





Just Paint It On The Threads

Use Smooth-On "No. 3" on all screw-thread joints, on steam or water lines, for ammonia lines, and for lines carrying hot or cold oil. Smooth-On "No. 3" costs slightly more than ordinary joint-making compounds, but the small difference is a cheap premium for insurance against leaky joints during the life of the pipe line!

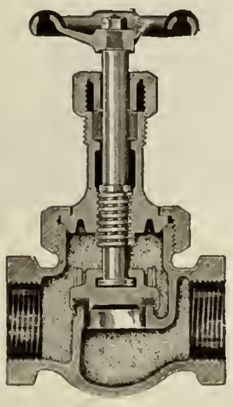
Smooth-On Cement "No. 3" is sold by Supply Houses, ready to use, in 1-lb., 5-lb. and 10-lb. tins.

☛ **Write for Free Sample**

THE CANADIAN ASBESTOS CO.
Dept. 52-G - Montreal, Que.

If your Supply House does not carry Smooth-On Cement "No. 3" send us their name and we shall see that you are supplied.

PRATT & CADY VALVES



It is real economy to install Pratt & Cady Bronze Union Bonnet Renewable Disc globe and angle valves. It is so easy to replace parts subject to wear that you are sure to take advantage of this feature.

P. & C. Folder No. 2 describes this valve in detail. May we send you a copy?

Furnace building has kept pace—

WITH greater commercial development came the call for higher boiler ratings. With higher capacities came jointless Plibrico Furnace Lining. Plibrico will withstand the over-ratings of the present day. It is a plastic lining that is pounded into place with a mallet and that, when baked, forms a seamless, rock-like wall that resists temperatures to 3,100 deg. F., that is air and gas tight and that far outlasts fire brick.

Plibrico is delivered only in steel containers of distinctive appearance as shown below.

Warehouses in 52 principal cities. Ask for 50-page booklet, "Modern Furnace Building."

DISTRIBUTORS: Beveridge Supply Co., Ltd., Montreal; Shell Bar Boico Supply Co., Ltd., Toronto; Evans. Coleman and Evans, Vancouver, B.C.; Winnipeg Supply and Fuel Co., Winnipeg; Gorman's Ltd., Calgary, Alta.

SONDERGLASS

"The Unbreakable Boiler Gauge Glass"

Two Glass Tubes in One

The different metals used allow for expansion and changes of temperature to which the glass is subjected, and add greatly to its pressure-resisting qualities, as each of these metals has different degrees of expansion. The inside of the tube expands in proportion to the temperature of the steam or hot water and the outside according to the temperature of the air.

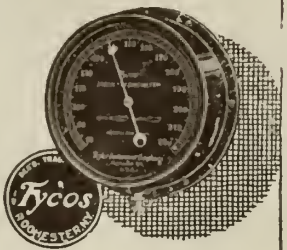
Tycos and the Economizer

It is as important to know the inlet and outlet water temperature as it is the incoming and outgoing flue gases passing through the economizer. *Tycos* Straight Stem or Angle Thermometers are used at these points unless inaccessible then *Tycos* index thermometers are used to bring the reading right to your instrument board.

Tycos Power Plant Catalog is within your reach—a postal brings it.



Taylor Instrument Companies
Tycos Bldg., 110 Church St., Toronto
There's a *Tycos* or *Taylor* Temperature Instrument for every purpose

Boiler Brand

The Simplest and Most Effective
FEED WATER TREATMENT

Silicate of Soda is the base of the majority of Boiler Compounds on the market—often made up under special names.

Boiler Brand is but one of our many grades of Silicate of Soda. It does the work of the most expensive compounds but as the engineer knows just what it is he can adapt it to varying conditions. Why bother with complicated treatments for the removal of boiler scale when the solution is so simple?

"Let a Technical Firm do a Technical Job"

The ANDERSON Steam Separator

will give you dry steam, under practically any working condition, at very low cost. It is one of the most reliable safeguards against the possibility of breakdowns caused by accumulation of moisture in engine cylinders or turbine casings.

The Anderson is made in both vertical and horizontal styles. Let us send you a catalogue.

THE V. D. ANDERSON CO.
West 96th St., Cleveland, Ohio

Mechanical Draft

Regardless of the size or the requirements of your power plant, Canadian Sirocco equipment of proper design is available. We offer a complete cooperative engineering service as well as the equipment of proven efficiency.

MAGNOLIA

Magnolia Anti-Friction Metal has been proven by U. S. Government tests to improve bearing service, effect saving in metal, power, fuel, lubricants, machinery parts and maintenance attention, and to be decidedly superior for its work. It is easy to handle, is absolutely homogeneous, and comes in convenient forms, for ready use. It will pay you to standardize on Magnolia Anti-Friction Metal. Its users invariably prefer it to lower grades.

Magnolia Metal Company, 113 Bank Street, New York

Chicago San Francisco Montreal

REG. U.S. PAT. OFF.

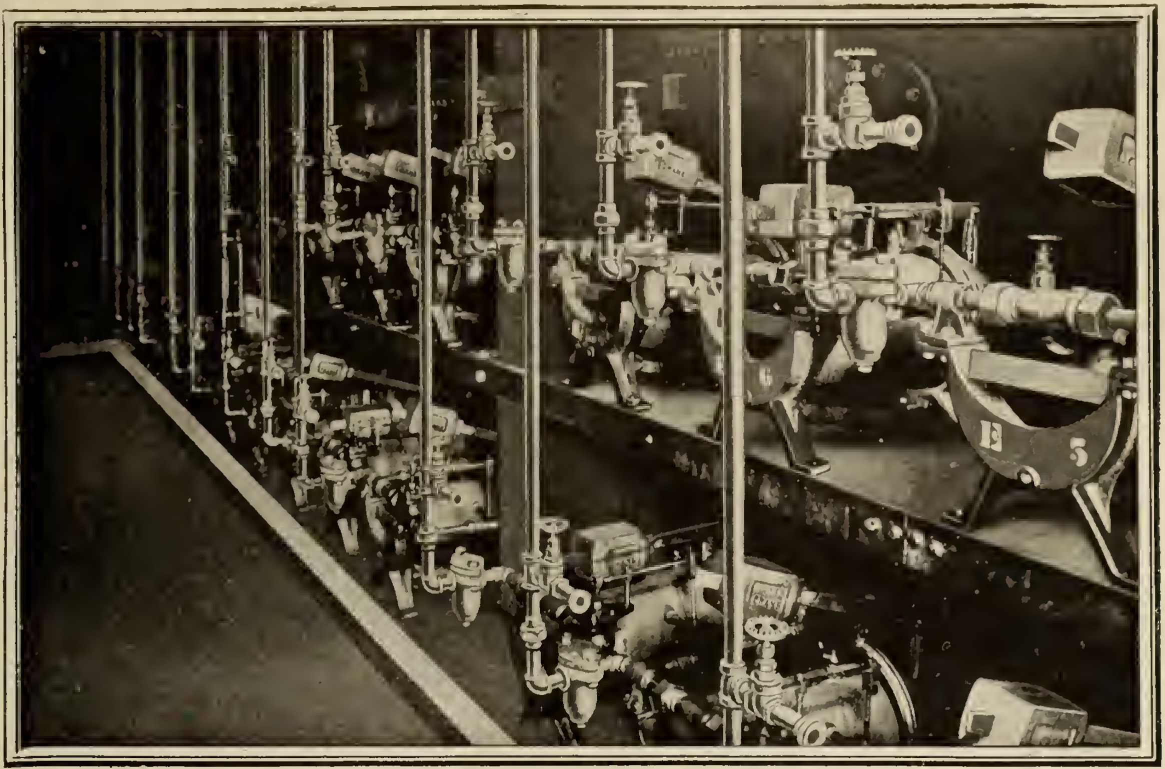
ANTI-FRICTION METAL

Stephen's Boiler Feedwater Treatment

Don't endanger your boilers with old-fashioned, expensive methods which are often ineffective. You'll find that the Stephen's Feedwater Treatment is not only more economical but ensures the removal of old scale and prevents the formation of new scale in absolute safety.

Consult our engineers. They are always happy to discuss your feedwater problems in a practical way without obligation to you.

Stephen's Chemical Mfg. Co., Ltd., 2 Johnston St., Toronto, Canada



CRANETILT STEAM TRAP INSTALLATION, ACADIA SUGAR REFINERY CO., DARTMOUTH, NOVA SCOTIA

INCREASING STEAM PIPE LINE EFFICIENCY

An increase in the efficiency of a steam heated process system can often be effected through the prompt removal of the condensed steam where it accumulates. The savings made possible by this practice may be lost, however, if the steam traps used do not function properly.

The visible operation of Cranetilt steam traps makes possible inspection at a glance. The positive action of the valves seals the pipe line against loss of steam into the condensation receiver.

Crane service provides thousands of devices and fittings which meet steam, gas, air, oil and water piping requirements of every description.

JENKINS

Extra Heavy Iron Body
Globe and Angle Valves

Maximum strength and rigidity are rigorously preserved throughout in the design and construction of Jenkins Extra Heavy Iron Body Valves. This reserve strength amply meets the strains and stresses due to expansion and contraction of piping or other causes.

These valves are suitable and guaranteed for 250 pounds working steam pressure, or 400 pounds working water pressure—the margin of safety is wide, for each valve before it leaves the factory is tested to 800 pounds hydraulic pressure.

The bodies of these valves are made of high-grade cast iron; the spindles are manganese bronze, having a tensile strength from 50,000 to 60,000 pounds per square inch. Regrinding discs and seat rings made of durable steam metal.

JEFFREY

Single Roll Crushers Are Built In Five Sizes

The 24 in. x 24 in. Crusher meets average requirements, such as Boiler Plants, Producer Gas Plants and Pulverized Coal Plants.

The 30 in. x 30 in., 36 in. x 36 in., and 36 in. x 54 in. sizes take Run-of-Mine coal and have large capacities, being generally used for service at the mine in reducing the entire output of coal to a size suitable for use with mechanical stokers, either in boiler houses or locomotive service.

The Jeffrey Single Roll Crusher

reduces Lump Coal to any desired size in a single operation —is easily adjusted—consumes little power—costs little to install—occupies little space—has rugged design and construction throughout — Efficient Safety Device protects against shocks and accidents.

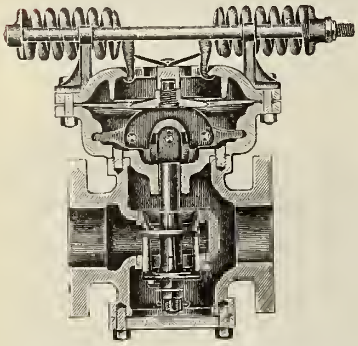
Foster Class "W" Pressure Regulator



The leader for general service on steam, air (certain conditions), and hot water, where delivery pressure is practically constant. It is standard for working pressures of 125 to 250 lbs.

Made in two weights.

For these Reasons—

1. A compensating spring movement exerting a uniform power on the diaphragm, without regard to the opening of the valve.
2. Renewable Seat Rings.
3. Ample Steam Capacity.
4. Drop forged steel stem, levers, toggle levers (case hardened) insuring durability.
5. No small parts to clog.
6. Ease of adjustment and accessibility for repairs.
7. No friction of parts. No dash-pot required. Noiseless in operation.
8. Small movement of diaphragm insuring long life.
9. Absolutely automatic after adjustment is made.
10. Great simplicity of construction and operation.

DURABLA

For smaller boilers, one of these stokers will meet your requirements

HUNDREDS of small and medium sized boilers in Canada are being fired by hand—are being fired by hand when one of these stokers (the type depends upon conditions) would cut costs and give better service, when one would meet requirements exactly.

Continuously and automatically the "Jones Standard Side Dump" Stoker and the "Murphy" Furnace feed the coal, burn it at maximum efficiency and discharge the ash. Fuel and labor costs are cut. Efficiency and capacity are raised. Smoke and clinker trouble are practically eliminated.

The Jones "Standard Side Dump" is for use with boilers requiring forced draft. It can be installed at moderate cost. Coal is burned by the superior underfeed principle and ash is deposited on side dump plates. Sudden peak loads can be easily met.

The "Murphy" Automatic Furnace is used where lighter, less fluctuating loads are met. It does not require forced draft. It is ideal for a great many smaller boilers where extreme combustion rates are not essential.

Ask for the separate bulletins which describe these stokers. Will you use forced or natural draft?

Do your Temperature Curves run

Zig-zag, like this?

or

Straight, like This?

Although you may **think** you are getting uniform temperatures in important processes involving the use of heat, you would probably be amazed if you could see the wide fluctuations that result from so-called hand "regulation."

The zig-zagging of temperature usually means waste of ingredients, spoiling the finished products, or lowering of quality of the goods, which means undermining your reputation. These conditions are permanently corrected by using the

SARCO

Temperature Regulator

No human hand can begin to compete with the Sarco. Responding instantly to the slightest temperature changes, it automatically admits or shuts off the steam, preventing excessive variations. Once set for a given temperature, **it maintains that temperature.**

The Sarco is entirely self-contained and self-operated. No electricity, compressed air, water or other outside agencies required, consequently it costs nothing to operate.

Has no perishable parts. No weights or levers to tamper with and throw it out of calibration. Not affected by temperature of room.

Write for Booklet J-77 and particulars about our free trial offer. You can try it before you buy it.

EMERGENCY Sluicing With

Sterling

THE ENGINE OF REFINEMENT

EMERGENCY Gasoline Engines

The dam at Traverse City, Michigan, was sluiced by the Winters Contracting Company of Detroit with two Union Centrifugal pumps, pumping 1,000 G.P.M. each against 435 ft. head, using two STERLING six cylinder gasoline engines at 1,400 R.P.M.

Exclusive of banked fires at night, cost of hauling coal 7 miles on clay roads, and salary of fireman, it would have cost $7.48 an hour for coal. STERLINGS did it for $6.69 an hour. Two engines (total) 420 h.p., on 306 h.p. load. Compare their cost at $23.00 a horsepower against the cost of a steam plant, and auxiliaries, and installing. As to dependability, one engine ran 53 days and one 83 averaging about 8 hours a day, and could have continued indefinitely.

STERLINGS can operate your reserve pump and generators. Cost you less initially, less to run, less to maintain, and require little space.

Sterling Engine Co.(Dept. C4)Buffalo, N.Y., U.S.A.

DETROIT NATURAL DRAFT STOKERS INSURE CHEAPER STEAM

You Reduce the Cost of Producing Power When You Install Detroit V-Type Stokers

Coal consumption is reduced 15 or 20 per cent, because it is possible to maintain overall boiler efficiencies of 70 to 75 per cent with Detroit Stokers, whereas good hand-firing practice shows 55 to 60 per cent boiler efficiency.

You save labor if you have several boilers, because one man can attend to them all.

You can burn lower grades of fuel with Detroit Stokers than can be burned successfully by hand-firing. This may enable you to save as much as a dollar a ton on your coal.

Detroit V-Type Stokers may be profitably installed in both tubular and water tube boilers. You can readily install them in connection with old boilers with little alteration.

Remember there is a complete line of Detroit Stokers—V-Type Overfeed for natural draft,—Single Retort Underfeed for forced draft with boilers up to 250 H. P.—Multiple Retort Underfeed for large boilers.

Bearing Metal plus Service

Ordinary bearing metals may look quite similar to Magnolia Metal, weigh the same, and cost even a trifle less. But when you buy Magnolia Metal, you get the assurance of long and efficient service as well as just so much metal. U. S. and other government tests have proven Magnolia Metal to have the lowest frictional coefficient of any known bearing metal and to have every other requirement for its purpose besides. Magnolia Metal melts and pours well, is easily peened and scraped in, and is always uniform in composition. It is perfectly adapted to a wide range of speeds and pressures, quickly adapts itself to inequalities in the shaft and embeds the grit that might score the shaft or increase friction. Try Magnolia Metal on one of your bearings and test its superiority to your own satisfaction.

The Simplest and Most Reliable of Feed Water Regulators

Just a straight expansion tube, connected to a balanced control valve—that is all there is to it. No springs or diaphragms; no pilot valves or needle valves; no floats or displacement bodies. The Copes is reliable, because it is mechanically right.

What it does—The Copes saves from 2% to 8% in fuel costs; it increases boiler efficiency, by momentarily cutting down the feed rate when there's a sudden increase in load, and by temporarily increasing feed water input when the load suddenly drops.

The Copes is used by nearly all of the large central stations; and a large majority of industrial plants. It is giving satisfactory service in every industry, and on every make and type of boiler.

The facts given here are merely an outline. Let us send you our latest bulletin. Drop us a line for Catalog "D."

BETTER REFRIGERATION

JAMISON

HAGERSTOWN MD., U.S.A.

Safety First!

The growing concentration of population in the cities of the nation imposes a correspondingly increasing tax upon the cold storage facilities of the country. The millions must be fed!

This industry in a large measure aids in the conservation of the health, life and comfort of the people through the proper preservation of food products. Hence the invariable application of the rule—"Safety First."

Be sure your plant is properly constructed and fitted with every modern appliance that will help in controlling humidity and maintaining temperature. Finally remember when all else is done, "Your Plant is Only as Good as Your Door."

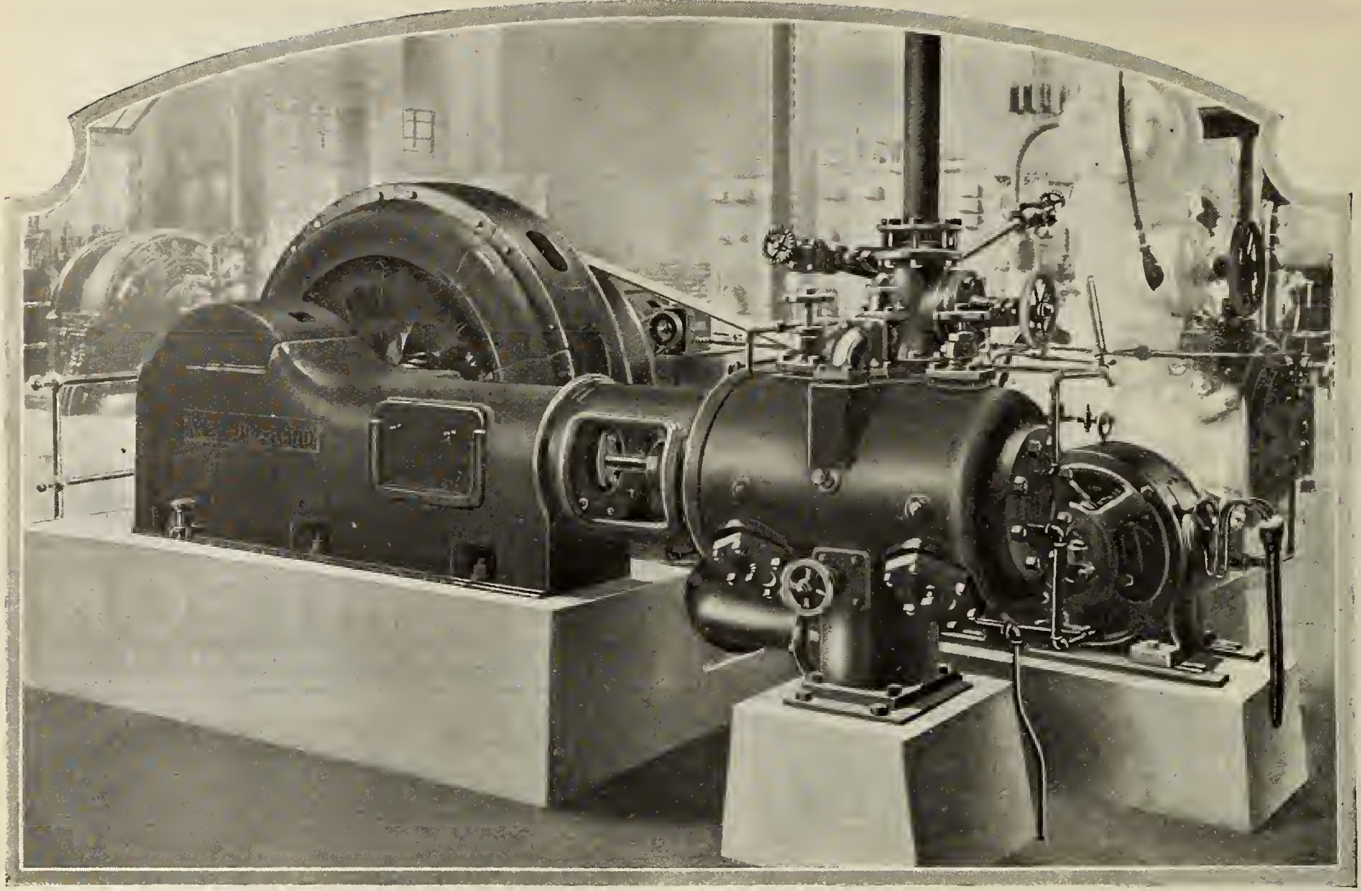
Jamison makes Doors and Windows in a scientific manner, built with brains rather than muscle, and representing 17 years' study of refrigerating and insulating problems. This is why they are better doors!

Architects and Engineers

Jamison Cooler and Freezer Doors, Cold Storage Windows and Automatic Ice Chutes made for all standard requirements. Also, built-in refrigerator fronts to specifications for all purposes when required.

If you have an interest in "Better Refrigeration" write for illustrated descriptive catalog. Address "Desk 11" please.

JAMISON Cold Storage Door Co.
HAGERSTOWN, MD., U. S. A.



At the Chateau Laurier

Dependence is placed on "Ingersoll-Rand"

For increasing the capacity of the refrigeration and artificial ice plant at its famous Chateau Laurier Hotel, Ottawa, Ont., the Canadian National Railways, chose an Ingersoll-Rand Class "PRE-2-A," Two Stage, Direct-Connected, Electric Motor-Driven, Ammonia Compressor, on account of its ability to meet, with highest efficiency, the varying demand for refrigeration throughout the year.

This machine takes over the load formerly handled by two old style, steam-driven units and supplies ice for icing water coolers on passenger cars and for table service at the Chateau. It also supplies refrigeration for a number of cold storage rooms and boxes at this famous hotel.

The Chateau is renowned for its cuisine, so that reliable refrigeration equipment is particularly essential. The load also varies considerably from time to time, so that a compressor permitting economical operation at under-load points is also necessary.

Ingersoll-Rand Ammonia Compressors meet the demands of modern ice and refrigeration plants in every essential and are backed up by the reputation and service of the largest manufacturers of air and gas compressors in the world.

Let our nearest branch help you solve your problems.

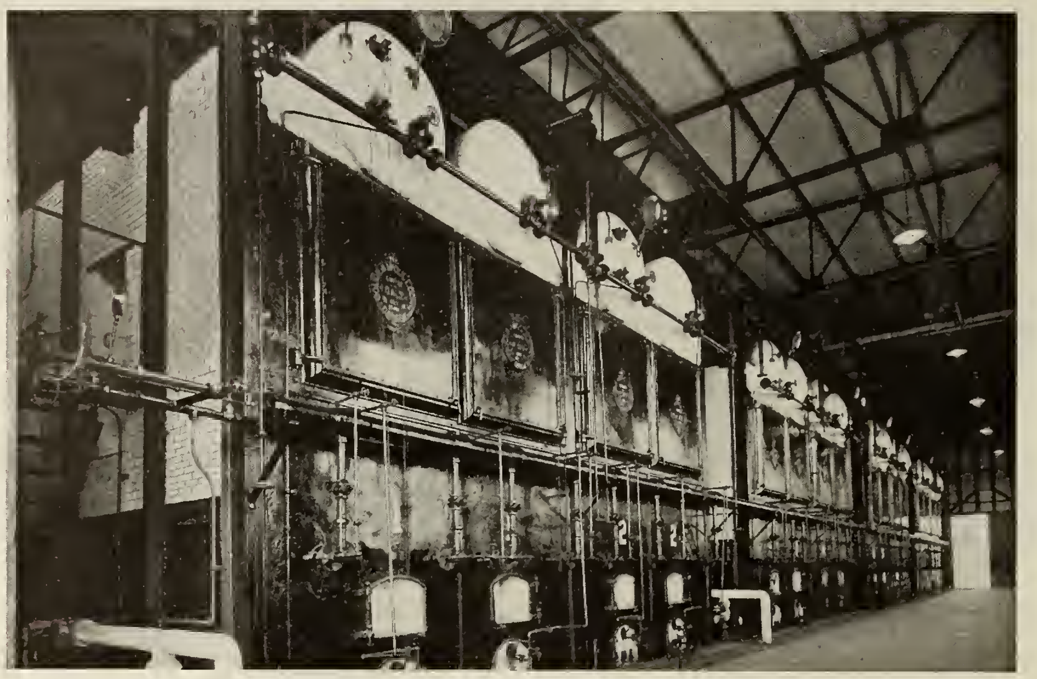
Goldie & McCulloch
Sectional Water Tube Boilers



One of several boiler rooms of the Imperial Oil Company, equipped with G. & McC. Co., Sectional Water Tube Boilers.

Provide Increased Steaming Capacity

Goldie & McCulloch Sectional Water Tube Boilers are equipped with large steam and water drums and connecting nipples of increased size. Thus they assure positive and rapid circulation and increased steaming capacity. These boilers are built to meet the demands of the largest plants. They are constructed of the best quality of material and all parts which are subjected to steam pressure are made of forged steel.

Goldie & McCulloch boilers are always drilled—never rivetted. They are thus built to stand up under the heaviest of strains that may be put upon them.

POWER HOUSE

ESTABLISHED 1907 *Toronto, July 20th, 1923* A SEMI-MONTHLY NEWSPAPEI

Economies of Refrigeration in the Power Plant

* By ARTHUR MURPHY

A Brief Outline of the Theory and Principle of Mechanical Refrigeration—The Vapor Compression and the Ammonia Absorption Types— Points for the Engineer to Observe in Cutting Costs

SINCE earliest times man has been faced with the necessity of cooling bodies below the temperature of the surrounding air. In tropical climates cooling drinking water by evaporation from the moistened surface of a porous vessel is a common procedure.

In more northern climes low temperatures in warm weather are secured either by the use of natural ice, harvested in the winter months and stored until required, or artificial ice manufactured as seasonable need demands. As every engineer knows, ice requires heat to the extent of 143.4 B.t.u. per pound to change from the solid to the liquid state, which heat must be supplied from some external medium, in the case of an ice box, for example, by the circulating air in it.

Since ice must change from a solid to a liquid state before any heat can be removed it follows that with ice alone a temperature lower than 32 deg. F. cannot be obtained. On the other hand certain mixtures such as salt and ice have a lower melting point than 32 deg. F., and under such conditions fairly low temperatures may be produced, as shown by the following table:

Per cent. salt in mixture by weight.	Temperature of mixture, deg. F.
0	32
5	27
10	20
15	11
20	1.5
25	-10

Ice is in wide use as a refrigerant in households, stores, dairies, refrigerator cars, and other places too numerous to mention. Although natural ice is widely used as a means of producing low temperatures, on account of high labor costs and transportation difficulties, it is often cheaper to produce ice by mechanical means at a point near the market than to harvest and store it.

The advisability of buying ice or installing a small refrigerating unit is a problem often confronting engineers in charge of the equipment in large public institutions, hotels, etc. It is largely a matter of first cost, convenience desired, local conditions such as temperature required, cost of power and distance from source of ice supply.

For the production of low temperatures by mechanical means the engineer in Canada has the choice of several types of machine, such as the air, the ammonia compression, the ammonia absorption, the CO_2 and the SO_2 machines.

Air Machine Simple

The simplest form of producing cold mechanically is by the compressed air machine. When air is compressed rapidly its temperature rises. This effect is readily seen in pumping air into an automobile tire. In the air machine, air is compressed in a cylinder, then the warm air is passed through coils surrounded by cooling water, which extract heat from it, lowering the temperature to approximately that at the inlet. The air is then passed through an expansion cylinder, its work on the piston causing a decrease in temperature, in other words the air does work at the expense of its intrinsic energy. This expanded air is at such a low temperature (possibly many degrees below zero) that it is capable of extracting heat from a room or space through which it may be passing either in pipes or in the open on its way to the suction of the compressor.

In practice the compression and the expansion cylinder are mounted on the same shaft, the expansion cylinder returning a portion of the work to the machine, but since friction is always present where there is motion of one part on another, and the cold air in the expansion cylinder occupies less volume than in the compression cylinder external energy is necessary to operate the system.

In the open system air is supplied to the compressor at atmospheric pressure and allowed to expand freely in the storage room. This necessitates a large machine for a given capacity, so the closed system is often adopted in which air is supplied to the compressor at 60 to 70 lbs. per sq. in. gauge and discharged at pressures from 200 to 250 lbs. gauge. In this way the size of machine is materially reduced, but a small auxiliary plunger or pump is required to supply a small quantity of air to the system in order to keep the inlet air to the required pressure.

The advantages claimed for the air machine are: simplicity of construction, ease of control and safety, as there is no gas used which would lead to an ex-

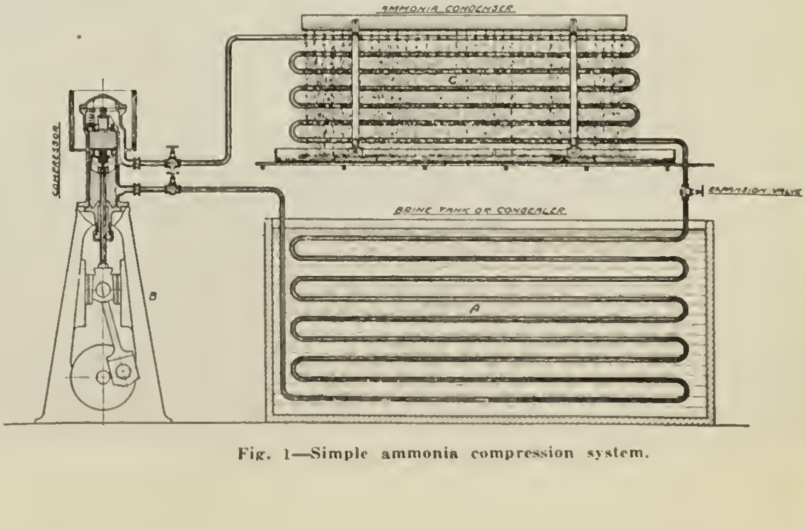

Fig. 1—Simple ammonia compression system.

---

*Editor, Power House.

plosion or loss of life in case of broken piping. The ease of recharging in out-of-the-way places in case of loss of working fluid, and the production of extremely low temperatures, 100 deg. below zero being readily obtainable, are other attributes of this machine which find favor.

The Vapor Compressor Type

In the air machine the working fluid is not condensed, therefore, no advantage of the latent heat of vaporization can be secured as in another system known as the vapor-compression type in which a vapor is raised by a compressor to such a pressure that on being cooled by suitable means to a moderate temperature the vapor is condensed, then allowed to expand at low pressure to a gaseous state.

In this type of machine ammonia (NH_3) is in wide use, although other substances, such as sulphur dioxide (SO_2), carbon dioxide (CO_2), methyl chloride, and mixtures of two or more gases are also used.

The table below will give the engineer some idea of the conditions necessary for machines employing the various vapors, assuming 70 deg. F. as the temperature of the fluid and 15 deg. F. as that of the cooling coils.

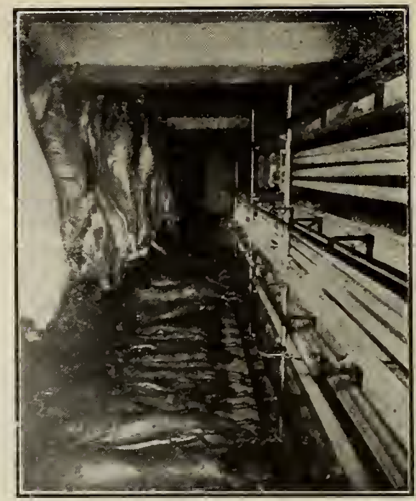
Pressure Lb. Per Sq. In.	Ammonia	Carbon Dioxide	Sulphur Dioxide	Ethyl Chloride	Methyl Chloride	Nitrous Oxide	Pictects Fluid
Suction	42.7	391	15.2	6.0	25.9	431	203
Discharge	129	847	49.6	20.0	73.3	832	51.6
Relative Volume per Unit Weight of Refrigeration	4.4	1	12				

The engineer, from a study of the above table, can form his own opinion as to the best type for his plant, bearing in mind local conditions such as temperature of cooling water and the space available. It can be readily seen that with ammonia the pressures and temperatures are moderate and for a given capacity the volume of fluid required is not excessive.

A simple vapor compression machine is shown in Fig. 1, consisting of a compressor, an expansion valve, a condenser and an expansion coil, surrounded by brine. Anhydrous ammonia at ordinary temperatures is a colorless liquid having a pungent alkaline odor weighing approximately forty pounds per cubic foot. Ammonia at ordinary temperatures and at 150 lbs. gauge pressure or over is in liquid form, if the pressure be reduced the liquid changes to a gas, taking up heat in the process.

The latent heat of vaporization of ammonia or the amount of heat required to change from a liquid to a gas is 565 B.t.u. per pound; the boiling point is about 27 deg. below zero. The simplest form of refrigerating apparatus would consist of but two parts, a tank containing liquid ammonia and a coil in which the ammonia could expand. As the liquid ammonia expanded and changed to a gas in the coil, after passing through an expansion valve, 565 B.t.u. would be removed from the medium surrounding the coil for each pound of gas used.

With such a simple apparatus the gaseous ammonia would then be wasted, and new liquid would have to be supplied continuously. In practice this would be much too costly so that escaping gas is piped to a compressor B (see Fig. 1) driven by external power, by means of which the gas is removed from the cooling coils A as fast as it is formed and compressed to a high pressure (150 to 200 lbs.). The gas then passes to the ammonia condenser C consisting of coils surrounded by cooling water in which the hot gases are cooled to such a degree that it is liquified. The cooling water extracts heat equivalent to that required to heat the ammonia from the temperature of the cooling water to the temperature leaving the compressor as well as the latent heat of vaporization. The liquid ammonia collects in a small tank below the condenser, from which it flows through an expansion valve to the expansion coils A completing the cycle. The liquid ammonia in changing to gas must take up heat which must be supplied by the medium around the expansion coils, in this case the brine. The CO_2 and the SO_2 systems work on exactly the same principle as the ammonia machine, the pressures used, however, are widely different. The ammonia type commonly works on suction pressures of 15 pounds and 180 pounds discharge, with the CO_2 1,200 is an average.



Beef cooler.

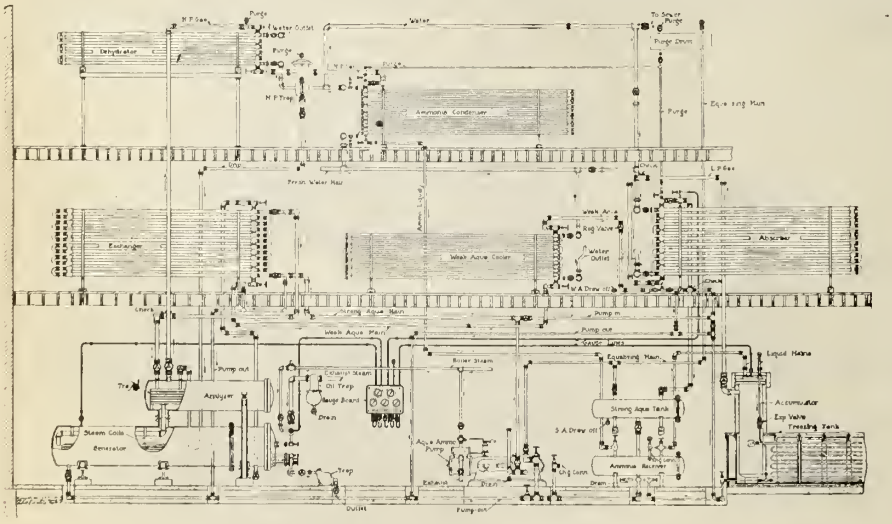


Fig. 2—Ammonia absorption system

Compressor Eliminated

The ammonia absorption system principle is in practice an alternative method of securing compression and liquefaction of the ammonia gas after it has expanded from the liquid form. Instead of a pump and mechanical power to compress the gas as in the compression system, heat and chemical action are the agencies employed to compress the gas to a point where it will liquefy, in the absorption system.

There are no moving parts except one small pump. Its action depends on the affinity of water for ammonia; a pound of water at 32 deg. F. will absorb .899 lbs. of ammonia or 1,180 times its own volume, at a temperature of 76 deg. F. it can dissolve only .45 of a lb.; at 190 deg. .122 lbs, and at 212 deg., but .074 lbs.

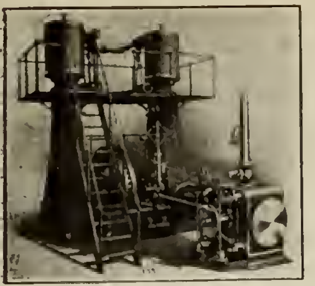
If a vessel of cold water be connected to the expansion coil filled with ammonia gas the water will absorb the gas so rapidly that the coils will be empty in a moment.

The simple absorption process absorbs the gas in a tank of water and then drives off the gas in a boiler or generator. As shown before, a low temperature will suffice, at 213 deg. F., practically all the gas will be driven out of the water. Four or five pounds pressure is sufficient to drive the gas off at a pressure of 150 to 170 lbs. per square inch, which will cause the gas to liquefy when cooled in the condenser—230 deg. F. is a common temperature in the generator.

Fig. 3 shows a complete absorption plant, each part and the direction of flow of the fluids being clearly marked.

Ammonia

Aqua ammonia is heated by steam in the generator, shown in the lower left of Fig. 2, driving off the ammonia gas at a pressure of 170 lbs. The gas then goes



Vertical Steam Driven Compressor.

through condenser coils, expansion valve and expansion coil, back to the absorber. A small pump then forces the aqua ammonia into the generator. To remove any excess heat and the heat supplied to the generator, the cool strong solution from the absorber flows over trays through which the heated gas from the generator is passing. In this way the liquor fed to the generator is heated and economy effected. The apparatus for this purpose is known as an analyzer.

Water vapor in the condenser would absorb some ammonia, reducing its efficiency, so is removed, on leaving the generator, by passing through tubes surrounded by cold aqua ammonia. This apparatus is commonly called a rectifier or dehydrator. A separator to remove any further moisture remaining is sometimes added.

To secure still greater economy the warm, weak liquor, on its way to the cooled absorber, is passed around the pipes carrying the strong solution to the generator. This results in an interchange of heat in the exchanger.

Though at first the process appears complicated, the mechanical equipment is simple, the only moving parts being in one small pump.

The system is capable of producing ice or refrigeration from exhaust steam which in many plants would otherwise be wasted. Another advantage lines in the fact that the system is closed, therefore, loss of ammonia is negligible over long periods of time.

The CO_2 and the SO_2 machines are in principle the same as the ammonia compression machine so need not be described again.

The CO_2 machine, working at high pressures requires care in packing and in pipe fittings. The advantage claimed for this machine is its small size; the cylinder is much smaller but the extra large flywheel required to give smooth running with the high pressures in the cylinder tends to make the overall size of the machine larger.

The chief advantage claimed for the CO_2 machine is that the gas employed, being non-poisonous, (as much as 8 per cent. can be breathed without danger), in case of accident, no lives will be endangered.

Insulation Important

The object of insulation or covering is to force the heat to flow in one direction only, in the case of a steam line along the pipe and not through the walls. For cold storage work the object of insulation is to keep heat out.

Heat travels in several ways, by radiation, by conduction, and by convection. It is impossible to prevent the passage of all the heat, but with the best insulations properly applied but very little loss occurs. A vacuum is the best insulator but dead gas is the only practical insulation medium for any service. The fewer and therefore the larger the air spaces in any insulating substance, the more readily will heat pass from one to the other. The best insulator is one containing the greatest number of the smallest possible air spaces.

On the market to-day there are several insulating materials which contain when new the large number of small air spaces necessary for efficiency in preventing the transfer of heat, on the other hand the requirements of cold storage demand that moisture will not impair its efficiency. Moisture is a good conductor of heat and thus any insulator for cold storage or refrigerating service must be moisture proof. Cork, ground and then baked into flat sheets or forms or held with a binder, find wide use to-day. Fibrous materials suitably waterproofed are also in use.

Experiments on cork board insulation gave a heat transfer as low as 6.2 B.t.u. per square foot per 24 hours per degree difference in temperature.

Obtain Clear Ice

Formerly the greater proportion of artificial or more correctly manufactured ice was made from distilled water, due to the difficulty of obtaining clear ice from untreated water, especially in districts where the water contained a fairly high percentage of impurities. Steam power was in use for driving the compressor, the exhaust steam then furnishing part of the heat necessary for the distillation of the water used in the manufacture of the ice.

With the increasing cost of fuels and the introduction of the electric motor for driving the compressor, the cost of distilled water became prohibitive, manufacturers of ice then turned to the city water supply, or other potable source. The difficulty of obtaining clear ice again confronted them, but the increased production from the same amount of power made it the only practical method.

With raw water, steam plants have been able to produce from 7 to 16 tons of ice per ton of coal, whereas with distilled water 4 to 8 tons per ton of coal was considered average.

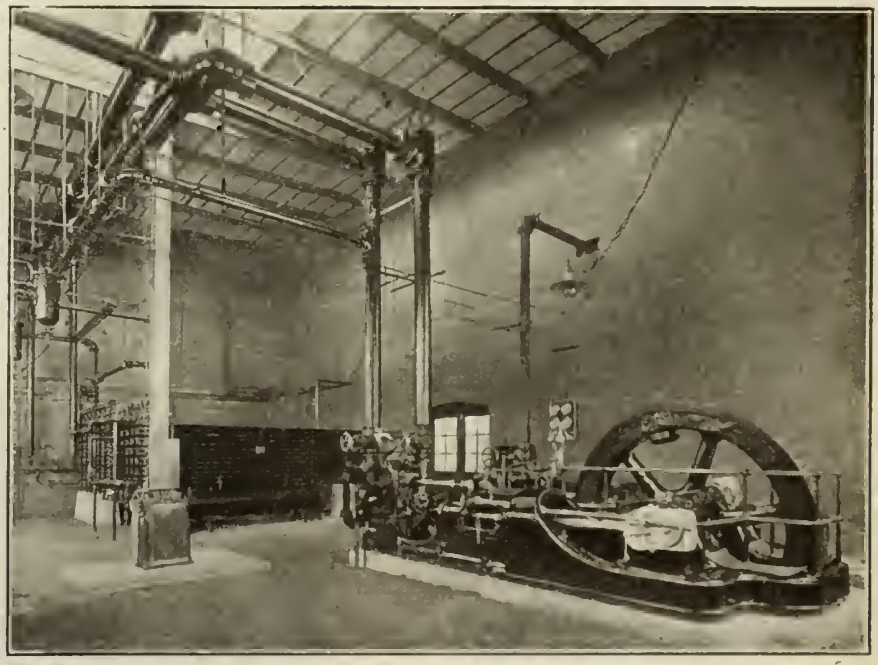
It was found that clear ice could be produced by air agitation of the water in the can during the time of freezing, the freezing surface being continuously washed by the movement of the water. When using raw water, white ice is caused by impurities, such as calcium carbonate, calcium sulphate, and magnesium salts.

The carbonates cause most of the trouble, fortunately they are easy to eliminate. Sulphates do not have to be removed. The greater the amount of impurities the water contains the more agitation required.

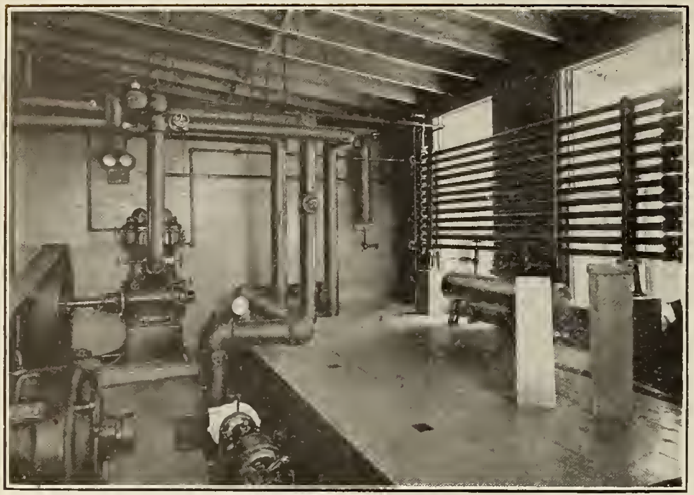
The process of freezing consists in the formation of small crystals of pure water in the form of ice; as the crystals form, the mineral salts, being more soluble in the unfrozen water than in the ice, are removed by the unfrozen water.

This occurs only with salts soluble in water, but carbonates of lime and magnesia are usually present, which, though insoluble in water, in the presence of free carbon dioxide, become soluble.

Water which is unsuitable for ice making should not be used. If the water contains a fair proportion of impurities



Horizontal Compressor, With Condenser in Rear



Small Ice Plant.

good ice can be made by sucking out the core and refilling with fresh water.

Detect Leaks

In the ammonia system any large leak is detected at once by the peculiar pungent odor present. This test is not sensitive enough for small leaks; a more reliable method is to make a sulphur torch by pouring some pulverized sulphur into a shallow laddle or large iron spoon and light with a match, then slowly pass along the pipe and fittings, keeping the torch as close to the pipe as possible.

Fumes from the sulphur coming in contact with the escaping ammonia immediately change the smoke from the sulphur torch to a whitish or foggy cast. Should any leak be found it will be necessary to pump out the ammonia and repair any defective pipes or leaking joints at once.

Another test is to hold acid (red) litmus over any suspected leaks. If the red litmus changes to blue it shows the presence of ammonia.

Ammonia may be leaking into the cooling water and being extremely soluble in water at ordinary temperatures may continue undetected for some time. Litmus or phenolphthalen is useful in detecting leaks of this nature as a very weak solution of ammonia in water will be shown. Jacket cooling water should be tested frequently with the aid of litmus and if ammonia be present the cover nuts of the jacket cover should be tightened sufficiently to stop any leaks.

It is unnecessary to point out the danger in entering a room full of ammonia fumes, to those who have had any experience with leaking equipment; less than 1 per cent. is fatal. Gas masks should be provided and every man in the plant should learn how to use one. Fortunately accidents from ammonia gas are extremely rare; on the other hand there is always a certain element of danger.

Oil Causes Trouble

Lubrication of the moving parts of a compressor is essential, resulting in the drawing in of minute particles of oil, which, if not removed by some means, will pass into the coils, forming an insulating coating on the inside of the pipes. Oil, being a poor conductor of heat, reduces the capacity of the condenser and materially cuts down the capacity and efficiency of the plant.

To overcome these effects of oil on the system an oil separator is placed between the compressor and the condenser. In principle the oil trap is similar to the steam separator. In some types the gas and oil entering at one side strike a series of baffles, in others a screen is used.

The engineer should drain the oil trap frequently, preventing any large quantity of oil passing into the system where it is sure to emulsify and clog the expansion valve. In draining oil from an ammonia system it is best to draw the oil off through a tube under water, then if any of the gas should escape it will be dissolved in the water. The smallest possible quantity of lubricant should be used in the compression cylinder.

Remove Air

The presence of air in the system is another frequent source of trouble, a small amount causing serious reduction in efficiency and capacity.

The system should be purged whenever the presence of air is suspected or after the head of the compressor has been removed. The packing around the rod should always be kept in the best possible condition, even then a small amount of air is sometimes drawn into the system when pumping out the suction side before shutting down the compressor.

Ammonia gas, being lighter than air, rises to the highest point in the pipes, therefore the air vent should be placed at a low point in the system. Carbon dioxide, being heavier than air, requires to be vented in the upper part of the piping system.

In purging air from the ammonia system it is advisable to blow the air through water. When air is escaping bubbles will rise to the surface. As soon as ammonia escapes a cracking noise is heard, similar to that made by blowing steam into cold water. It is then an indication that the air has been driven out and that ammonia is being wasted. With carbon dioxide it is more difficult to tell when the air is removed, a simple method however is to hold a large milk bottle to the vent, when, if a lighted match is extinguished the instant it is dropped into the bottle, carbon dioxide is escaping and the vent should then be closed.

Care of Brine

Engineers in charge of refrigerating plants are usually careful about proper lubrication, cooling water, and the prevention of leaks, but pay little attention to the condition of the brine. The tendency is to make the brine too strong, on the other hand sufficient salt must be used so that the freezing point will be low enough to prevent a freeze-up in case of failure of the brine pump for a short time and a consequent lowering of the temperature in parts of the system.

The thermal capacity of brine decreases as its density increases, or in other words, a weak brine can carry more heat than a strong brine, as the following table for calcium will show:

Deg. on Salomiter at 60° F.	Deg. Baume at 60° F.	Per Cent. Calcium Chloride	Freezing Point Deg. F.	Specific Heat
4	1	1	31.10	.996
72	18	16	10	.854

Disposing of Condensation in the Power Plant

Little Steam Find its Way to the Atmosphere in Modern Practice and Equipment Must Have Capacity Nearly Equal to That of Boiler Feed

IN ONE way or another all the water evaporated in the boilers of a steam plant must be disposed of after it has performed its work in the generation of power and the furnishing of heat for various purposes.

In the old-time plant, where the exhaust from the engine was discharged outbound, and condensation within the piping blown out through open drips, without the use of traps, the matter of damage was a comparatively simple matter.

At the present time very little steam finds its way to the atmosphere, and the equipment for handling the condensation must have a capacity very nearly equal to that of the boiler feed.

System Complicated

In many ways the drainage system is much more complicated than the feed system, because, in the latter case, the water is usually taken from a single source and fed to the boilers by a single pump or pair of pumps working together.

On the other hand, the condensation must be collected from a large number of points, some of it being pure water which may be returned directly to the boilers, while other portions contain oil which must either be renewed or the water drained into the sewer.

Instead of flowing directly to a common receiving tank, the condensation must be discharged through traps to avoid the waste of steam, and again great care must be taken in the arrangement of the piping to prevent the accumulation of water at different points, and also any interference in the action of traps or pumps discharging into the same system of piping.

In order to simplify matters, let us first follow the steam from the boiler and collect the condensation in groups, and then see how these are best disposed of. The sources of condensation will, of course, vary in different plants according to local conditions, and it will be necessary in the present connection to include a considerable number to cover ordinary cases in a variety of plants in Canada.

When condensing engines or turbines are used, the disposal of the condensate will depend upon the type of equipment employed. If a surface condenser is used, the condensed steam is discharged into a hot-well by a suitable pump and returned to the boilers with the make-up water.

With reciprocating engines the exhaust should pass through an oil separator on its way to the condenser, and in some cases it may be necessary to filter the condensate also before discharging it into the hot-well. If there are other oily drips to be cared for it is sometimes more convenient to place the filter between the hot-well and feed-pump.

In a non-condensing plant the exhaust, in ranging proportions, is usually employed for heating the buildings, for process work, and in warming water for domestic purposes or for feeding the boilers, so that a variety of apparatus must be made use of in handling the water of condensation from these different sources. In addition to the above there is condensation which takes place in the distributing pipes of a steam plant, both in the power, heating, and industrial systems, which must be taken care of.

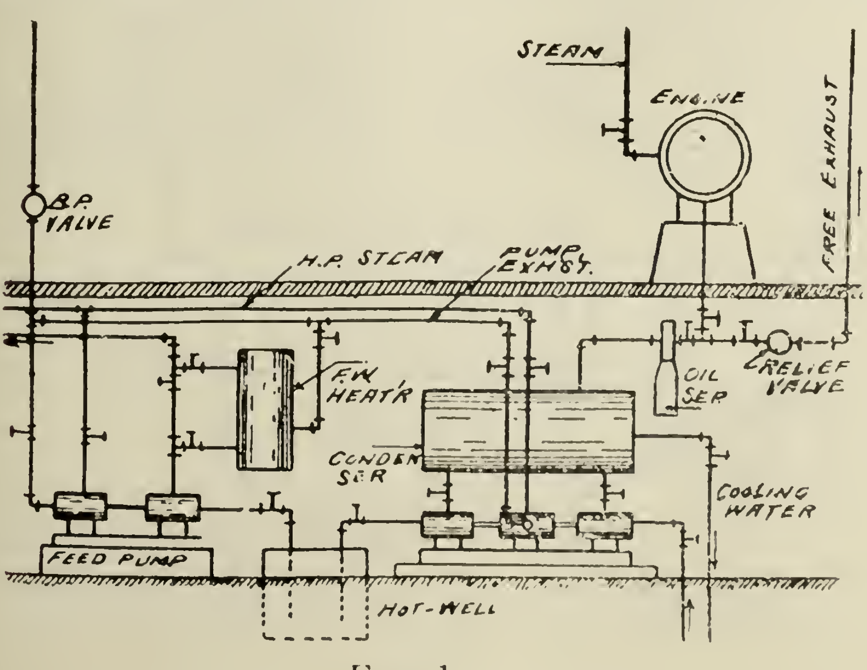

FIG. 1.

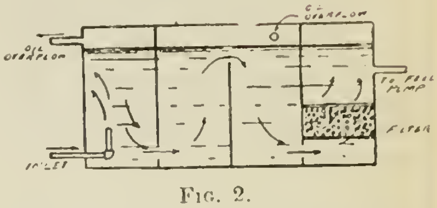

FIG. 2.

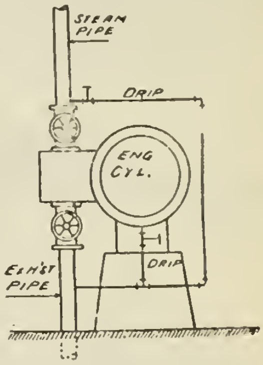

FIG. 3.

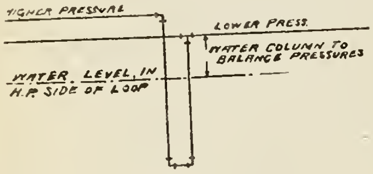
Having roughly divided the sources of condensation into groups let us now see how it may best be handled and what equipment is required under different conditions.

A typical layout for disposing of the condensate from a reciprocating engine connected with a surface condenser is shown diagrammatically in Fig. 1. The exhaust from the engine passes through an oil separator into the condensing chamber from which the condensate is removed and discharged into a hot-well as previously described. If special precautions are required or there are other oily drips to be cared for, the hot-well may be separating tank and filter of the general type shown in Fig. 2. The exhaust steam from the condenser pump and feed-pump is utilized in a feed-water heater the drip from which is usually trapped to the sewer on account of the oil.

In large plants where the heat in this water would amount to considerable proportions and where water is valuable, an oil separator may be placed in the pump exhaust, as shown in the illustration and the condensation trapped to the hot-well from which it may be returned to the boilers with that from the main engine.

In case a jet or barometric condenser is used, and the cooling water is suitable for boiler feeding, an oil separator may be placed in the main exhaust pipe, as in Fig. 1, and the feed-water drawn directly from the discharge from the condenser, a portion being diverted to a hot-well or receiver for this purpose. In this case it will not usually be necessary to filter the water if an efficient oil separator is employed, as the condensate will be diluted with thirty to fifty times its weight of cooling water. When a turbine is employed instead of a reciprocating engine, the general arrangement will be the same, except for the oil separator in the exhaust line, which is not needed.

In the case of non-condensing engines the exhaust steam passes on to other pieces of apparatus, except for any surplus which is discharged outbound, and the disposal of the condensation will be taken up later. There are, however, two or three details of drainage at the engine which may well be mentioned at this point, and which are common to both condensing and non-condensing machines.



HIGHER PRESSURE
LOWER PRESS.
WATER COLUMN TO BALANCE PRESSURES
WATER LEVEL, IN H.P. SIDE OF LOOP

FIG. 7.

The first of these is shown in Fig. 3, and applies to cases where the steam separator is located some distance away from the engine or where a single separator in the main steam line is made to serve several units. This is for draining away the water which collects above the throttle valve, and is to be used only a short time before starting up the machine. Although water at this point contains no oil, it is usually discharged into the exhaust pipe with the drip from the cylinder cocks, as the quantity is small.

The throttle and cylinder drip pipes are commonly given a uniform diameter of ½ in. except in the case of large machines, as they are not expected to take care of any large rush of water, and there is no advantage in increasing the size to any extent.

A typical method of draining the jacket and receiver of a compound engine is illustrated in Fig. 4, in which case steam at boiler pressure is supplied to the jacket of the high-pressure cylinder and passes from here, with any condensation which has been formed, into the receiver, then through the tubes to the jacket of the low-pressure cylinder, as indicated. The condensation from the high-pressure steam chamber of the receiver, and from the jacket of the low-pressure cylinder, is trapped into the shell of the receiver, and, being at a high temperature, breaks into steam when discharged into a lower pressure and mixes with the steam passing through the receiver from the high- to the low-pressure cylinder. Condensation from the low-pressure chamber of the receiver, together with any unevaporated water from the discharge of the high-pressure traps A and B, is drained to the hot-well through trap C.

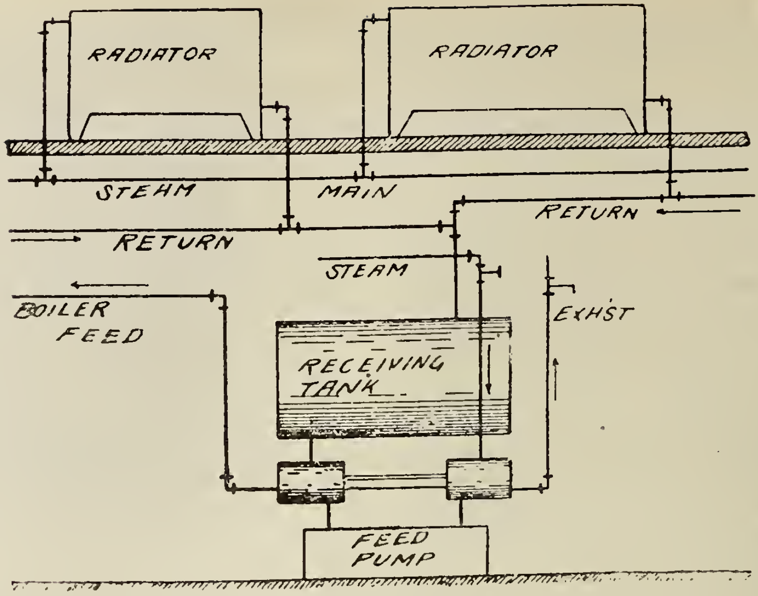


FIG. 5.

The disposal of the water of condensation from a heating system is of great importance, as the successful operation of the plant is as dependent upon this as upon a supply of steam to the radiation.

In the gravity arrangement, shown in Fig. 5, the water flows by gravity from the radiators through properly graded return pipes to a receiving tank, from which it is pumped back to the boilers. When exhaust steam is used for heating, in the average industrial plant, office building, or institution, it should, of course, be passed through an oil separator before entering the heating system, and the same precautions taken for filtering the return water as already described in connection with condensing engines.

When there are various drips to be taken care of, coming from systems or apparatus under different pressures, the tank should be vented to the atmosphere and the return from each system discharged into it through a trap. If the condensation all comes back under practically the same pressure the traps may be dispensed with and a closed receiver used.

In this case each separate return line

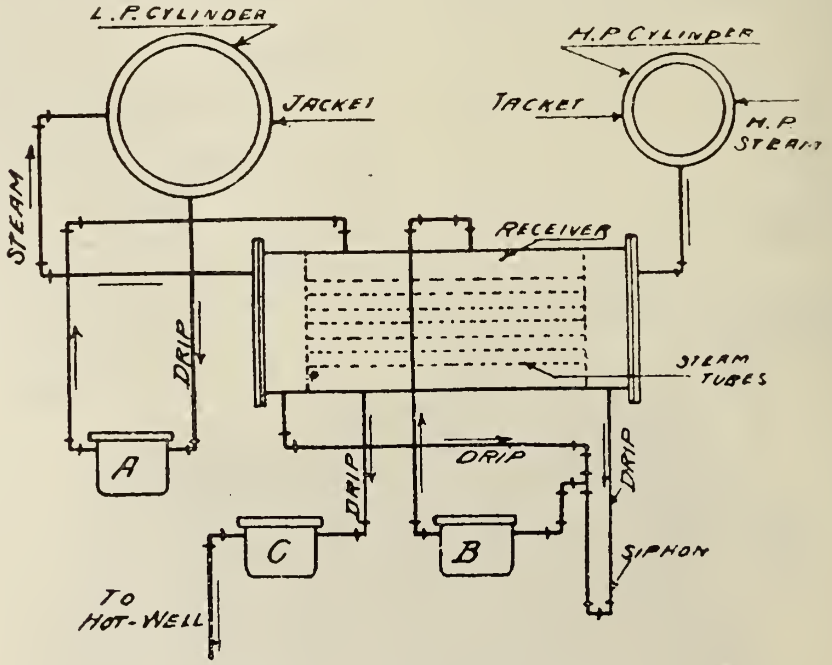

FIG. 4.

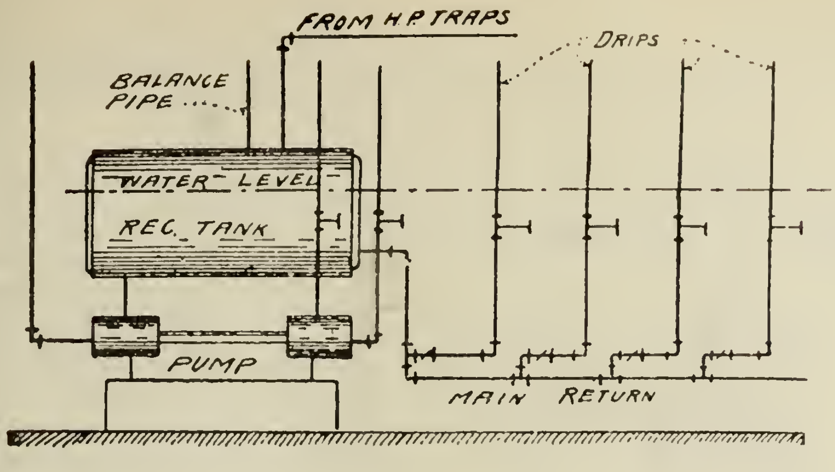

Fig. 6.

should be sealed and provided with a check-valve, as shown in Fig. 6, to prevent any "backing-up," or water-hammer, due to slight variations in pressure which are always present in different return lines, even though under the same initial steam pressure.

It is not good practice to allow a high-pressure trap to discharge into a sealed return or into a receiving tank below the water line, if these are under a lower pressure, as water-hammer and snapping will nearly always result. When water under a high pressure and temperature is discharged into a lower pressure it first breaks into steam, and if this action takes place under water the sudden condensation which follows will produce considerable disturbance of the kind mentioned above.

If the discharge from the high-pressure traps is brought into the receiving tank above the water line, as in Fig. 6, any steam which is formed will pass into the low-pressure system through the balance pipe. If the quantity of steam thus formed is small, and the balance pipe of good size and connecting with a large return, it will do no harm; but if a considerable quantity of steam is liberated in the tank at a somewhat higher pressure it will tend to unbalance the pressures existing in the return system and hold back the condensation in some of the connecting pipes.

Under conditions of this kind it is best to insert a trap in the main return line and vent the receiver to the atmosphere. Care must always be taken to equalize the pressure in the return lines of a heating system by water-seals where two pipes join, either by syphon loops or by carrying the return mains below the water line in the tank or trap. Arrangements for this purpose are shown diagrammatically in Fig. 7, in which case any difference in pressure due to inequality and length of run will be balanced by the water-seal in the loop or drop pipe.

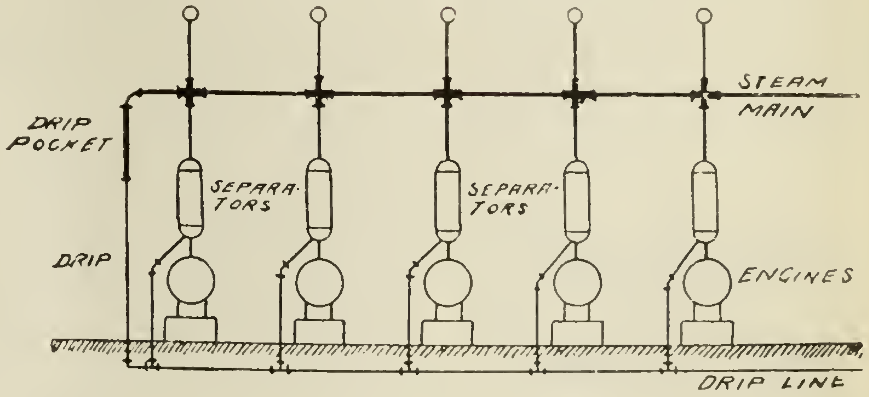

Fig. 11.

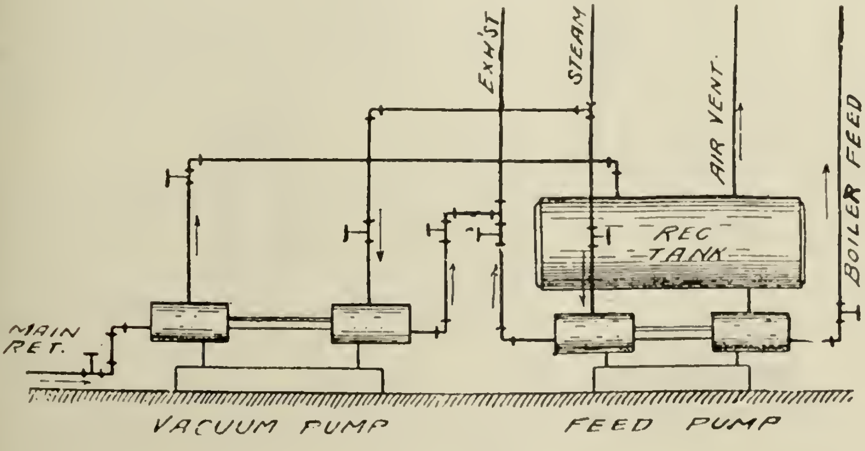

Fig. 8.

The return connections and disposal of the condensation in an "air-line" vacuum system will be the same as for the ordinary gravity system just described, as only the air-valves are connected with the vacuum pump. When the "return-line" vacuum system is employed, the general arrangement is similar to that shown in Fig. 8, although details may vary in different cases. In this system loops and water-seals are not required, as the entire return system of piping is under a suction which takes care of all minor differences of pressure.

In the ordinary arrangement, shown in Fig. 8, the mixture of air and water from the heating system is discharged by the vacuum pump into a vented receiver, where separation takes place, and from which the condensation is pumped back to the boilers, the same as in the other two systems previously described. In special cases, with certain types of vacuum pumps, the feed-pumps are omitted and the water discharged directly into the boilers, air separation taking place in a special receiving tank before the water reaches the pumps.

The return of condensation from process work, domestic water heaters, etc., is combined with that from the main heating system, and usually consists in discharging it by means of traps into the main receiver or hot-well to be returned to the boilers with that from other sources. If the condensation from some special piece of apparatus is small, and the machine remote from the receiving tank, it may not be worth while to save it, but in general all hot water should be returned to the boilers and its heat utilized.

The drainage of high pressure piping has been touched upon indirectly in connection with the low-pressure work, but requires special mention in regard to certain points of drainage in the boiler- and engine-rooms. One of the most important details of this kind is the drainage of the main header.

Water in high-pressure piping is par-

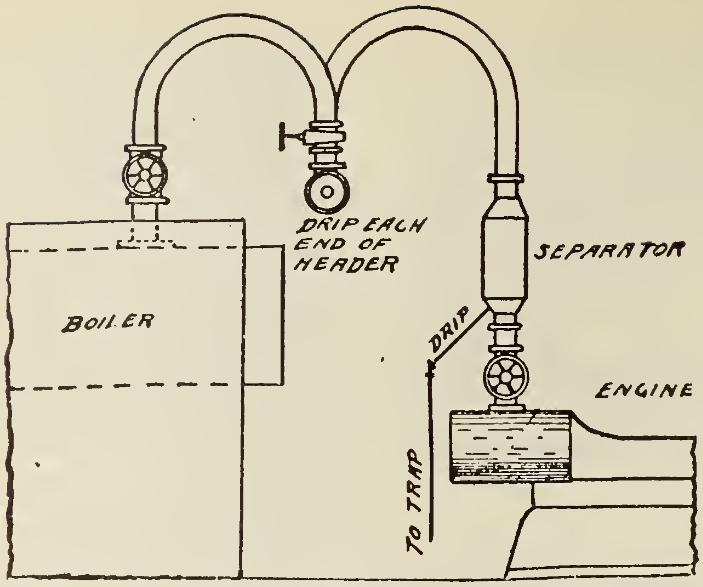

Fig. 9.

ticularly dangerous, for if carried into the engine cylinders in considerable quantity it is liable to wreck the engine or at least rupture the cylinder heads; and condensation in the mains is likely to produce water-hammer, which in turn causes vibrations tending to loosen the joints.

Water in sufficient quantities to produce slugs the full size of the pipe is capable of serious damage when steam is first turned on or sudden changes in pressure occur in the system. The presence of moisture also reduces the efficiency of an engine as it increases the rate of heat transfer from the steam to the cylinder walls. Water finds its way into the piping in two ways: first, by condensation; and, second, by being carried over in the form of spray. The first may be reduced by suitable insulation, and the second by improvements in boiler design.

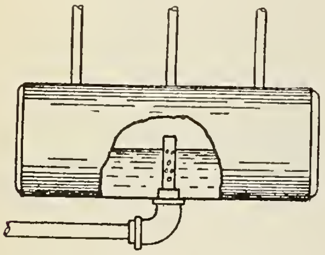

Fig. 1

Under the most favorable conditions a certain amount will collect in the piping, and must be removed by a drainage system of a form adapted to the existing arrangement of piping as found in each individual plant. While there are certain general rules to be followed, it is not always easy to tell what changes are taking place inside the piping, and each case must be studied separately. One point which applies to all plants is that maximum conditions must always be provided for. A drainage system may have ample capacity for normal conditions, but prove inadequate when steam is first turned into the cold piping, when water is carried over from a foaming boiler or when an additional unit is cut in too rapidly. Conditions at such times not only throw an extra load upon the drainage system, but, owing to the unbalanced pressure, slugs of water are liable to be driven through the pipes with sufficient force to fracture fittings where changes of direction take place.

Separators are relied upon to prevent water from reaching the engine cylinders, but these should be supplemented by a sufficient number of drips to remove the condensation from all unavoidable pockets or low points in the piping between the boilers and engines. When the piping is arranged as shown in Fig. 9 each end of the main should be drained in addition to the drips at the separators. In general, a separate trap should be provided at each end discharging into the receiving tank.

When the engine-room is at some distance from the boilers, and the flow of steam through the main is in one direction, the scheme illustrated in Fig. 10 may be employed with satisfactory results. In this case the main should be kept full size for its entire length and end with a pocket or reservoir to catch any sudden rush of water. The drainage from this pocket and the various separators may enter a common drip line leading to a trap discharging into the main receiver or to a system which returns the water directly to the boilers.

Trade Catalogs

A new style of centrifugal pump called a "series pump" is described in a catalog just issued by the De Laval Steam Turbine Co. In this pump double suction impellers and volute diffusers are used, as in single-stage centrifugal pumps. The connecting passages from stage to stage, however, are included in the pump case castings, as in the ordinary multi-stage pump. The advantages claimed are, perfect hydraulic axial balance and high efficiency under varying loads, as is characteristic of the single-stage pump. These series pumps are made with two or three stages. Where more than three stages are required, the use of two independent pumps operating in series and mounted on a single base plate is recommended in order to keep down the length of shaft between bearings.

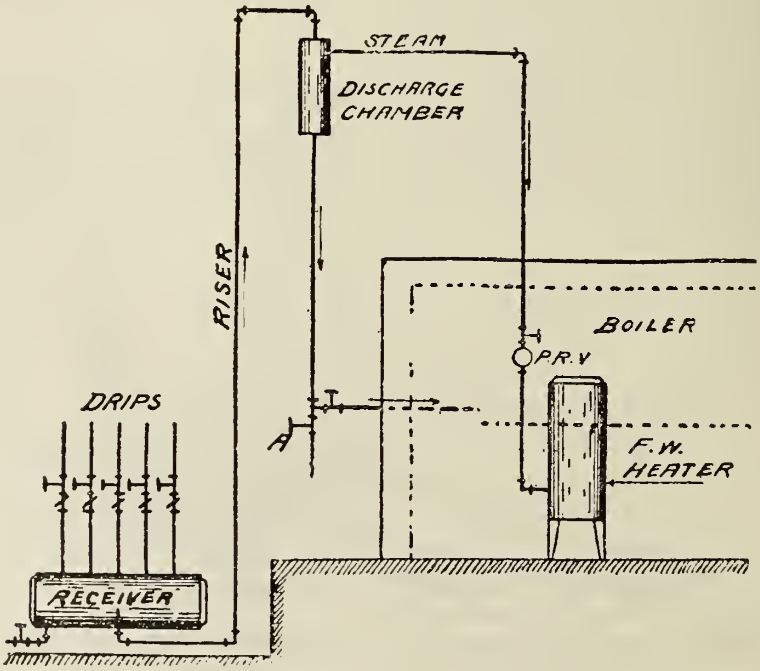

Fig. 10.

Excess Air Costly Factor in Boiler Operations

Experts See Increase in Efficiency of Steam Generation When Accurate Measurements of Air and Fuel Supplied as Well as Water Evaporated Can be Obtained

THE introduction of practical instruments for the measurement of very large volumes of gases has at last rendered possible the ideal for efficient steam generation—the continuous measurement of the air consumption.

A boiler plant is essentially a factory or process equipment for the production of steam at a given temperature and pressure, and the main raw products or ingredients are fuel, water, air, and labor.

If we are going to produce steam in the most economical and scientific manner, that is, work the boiler plant at the highest efficiency, it is necessary to keep a continuous and complete record of the labor costs, the amount and analysis of the fuel burnt, the amount and analysis of the water evaporated to steam—that is the production of the plant— and last, but not least, the amount of air used.

Labor Costing Simple

Labor costing is, of course, a simple matter, although most firms do not even do this properly. The continuous record of the coal or other fuel consumption is also quite easy, various automatic coal-weighing machines being on the market.

As regards the output of the plant, there are over twenty different feedwater meters and about ten steam meters available, so that here again no difficulty is experienced by anyone who desires to generate steam on efficient lines. As is of course well known, however, hardly any steam user adopts these obvious methods, even in electricity generating stations, and probably something like at least 90 to 95 per cent. of steam users in Canada have no accurate method of determining the output and true performance figures of the boiler plant. The consequence is that the average net working efficiency of boiler plants is only about 58 per cent.

Excess Cold Air

One of the great difficulties of maintaining a high figure is the trouble in connection with the prevention of excess of cold air passing through the fires, and boiler plants in general are at present being worked with an average of 75 to 100 per cent. excess air, that is, 20 lb. or over of air, or, say, 250 cubic feet at N. T. P. per pound of average semi-bituminous coal as compared with the theoretical figures of, roughly, 11.5 lb. air per pound of steam coal, or, say, 142.5 cubic feet at N. T. P.

This state of affairs is also indicated by the CO_2 figures in the flue gases. The table following is the result of over 400,000 determinations of CO_2 taken in nearly 400* power plants, giving an average percentage of CO_2 of 7½ per cent. corresponding to 27 per cent. theoretical loss in the coal bill from excess air.

CO2	Number of plants	Figure expressed as a percentage
12 per cent. and over..........	10	2.5
11 per cent	10	2.5
10 per cent.	39	9.75
9 per cent.	48	12.0
8 per cent.	60	15.0
7 per cent.	91	22.75
6 per cent.......	58	14.5
5 per cent.	51	12.75
Less than 5 per cent.	27	6.75
	394*	98.5

*Six plants in which figures were not reliable.

Assuming 12 per cent. CO_2 as a reasonably correct figure in practice, corresponding to 17½ per cent. theoretical loss, the actual saving to be obtained in the coal bill by increasing the percentage of CO_2 from 7½ to 12 per cent. would be about 9½ per cent.

> **The greatest enemy of progress is the closed mind. The engineer, the manufacturer or any one else who says, "This is my work," and will not learn and think beyond the day's need, is not only refusing to permit his own development, but is restricting his capacity for usefulness. The work that carries civilization forward in the service of mankind will ever be done by the individual. The leaders will be those not born but self-developed to a superior usefulness. And, happily, development comes to any man who permits himself to "grow."**

As we gradually reduce the excess air in the furnace, the percentage of CO_2 is increased in some corresponding proportion until we get to a point where CO and unburnt gases appear in spite of the presence of actual excess air. This point depends in practice on various conditions, chiefly the quality of the coal, but roughly it is about 14 per cent CO_2, which is equivalent to a 15½ per cent. theoretical loss in the coal bill owing to excess air.

Net Result a Loss

If now this figure for CO_2 is put up to 15 per cent. the net result is a loss. The theoretical saving obtained by raising the CO_2 from 14 to 15 per cent. is 1 per cent. of the coal bill (15½ per cent. theoretical loss—14½ per cent. theoretical loss) but there is at the same time a serious loss of about 7½ per cent. due to CO and unburnt gas, so that the net result is a loss of 6 per cent. in the coal bill in spite of the reduction in the amount of excess air, whilst a further increase to 16 per cent. CO_2 would give an enormous loss, and 17 per cent. CO_2 is equal to the excess air loss of only 5 per cent. CO_2—33 per cent. theoretical loss.

The "critical point of efficient combustion" is given by the highest CO_2 with absence of CO and unburnt gas, and it is obtained with roughly 12 to 17½ per cent. excess air for ordinary coal with mechanical stokers or hand firing.

The use of modern automatic flue gas analysing machines, therefore—either machines for determining both CO_2 and CO and unburnt gases continuously and giving a record of the results side by side on the same chart, or for determining both CO_2 and oxygen—are invaluable. But even duplex instruments in themselves are not sufficient, and what is really required is to enclose the whole boiler plant and admit the air under just as good control and measurement as the fuel and the water.

There is no practical objection to this plan from the point of view of the building, especially in the modern power station plant, for the whole installation can be enclosed so that all the air required enters through one central trunk or shaft. The doors can be of the double variety so as to be absolutely air-tight when the attendants pass in and out for the coal when entering, and for the ash and clinker when leaving.

In this trunk may be placed a modern type of large volume metering appliance. The average gas meter type of apparatus through which all the air would pass, is, of course, hopeless because of the size and expense.

Principle Gains Favor

The principle now gaining favor in Great Britain is that of the "Pitot" tube or "Venturi" disc, according to circumstances, as in steam meters. The slight difference in pressure, proportional to the volume of air flowing in the "Pitot" tube circuit, or in the neighborhood of the disc of slightly reduced internal diameter, is recorded by a suitable recording mechanism in terms of cubic feet of air, which must be corrected for temperature and barometer.

There is no difficulty about this correction, as the volume of air to be measured is not particularly great in com-

(Turn to page 46)

Practical Ideas From Practical Men

WATER COOLING

Here is a kink that may prove to be worth many dollars to the person who considers it safe to make a water cooler along the lines indicated in Fig. 1.

The writer was once connected with a company that made some water coolers in this way. The method was the first one that entered the head of the chief engineer and it looked perfectly logical to the rest of us. No doubt it has been used many times and perhaps it has been used successfully. I saw the method recommended in a refrigerating paper not long ago as being a good, dependable method,—but, Beware!

As shown, an ammonia coil is placed inside of a closed cylindrical tank for cooling the water. The water is supposed to be kept in continual motion, and if a sufficient quantity of water is circulated the method may be perfectly safe. But there is danger that circulation will not be maintained or that the temperature of the water will reach such a low point that the water begins to freeze, and when it begins to freeze —look out. The tank will burst due to the freezing and it will be found very difficult and costly to repair.

Fig. 2 illustrates a much better method —a method that is practically foolproof. The ammonia coils are placed in an open tank, as indicated, close to the top of the water level. Please note that the liquid in the open tank is not brine but is plain ordinary water. This water can freeze if it wishes to but of course it will freeze only at the top. The tank is made large enough so that it is not likely that the water will freeze clear over to the walls of the tank, consequently there will be no rupture. The coil being close to the top of the water where the water is always warmest, proper circulation is maintained. That is, as soon as the water cools it moves downward and the warmer water comes upward. The cold water therefore surrounds the lower coil, which is the water coil.

The temperature of this surrounding water will never be lower than 32 deg., consequently the water in the lower coil will not freeze and of course the water surrounding the lower coil will not freeze, as all of the freezing takes place at the top. In this way, circulation of water through the lower coil is always possible and there will be no clogging. In Fig. 1, in case the water should freeze solid, there would be no circulation of water.

Since the cylinder tanks shown in Fig. 1 were taken out and the open tanks similar to Fig. 2 installed, no difficulty from freezing has been experienced. Freezing of the water in the lower coils is impossible under regular working conditions.

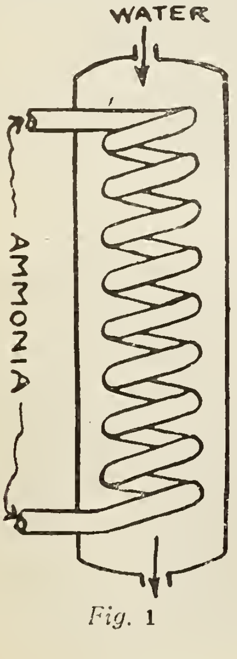

Fig. 1

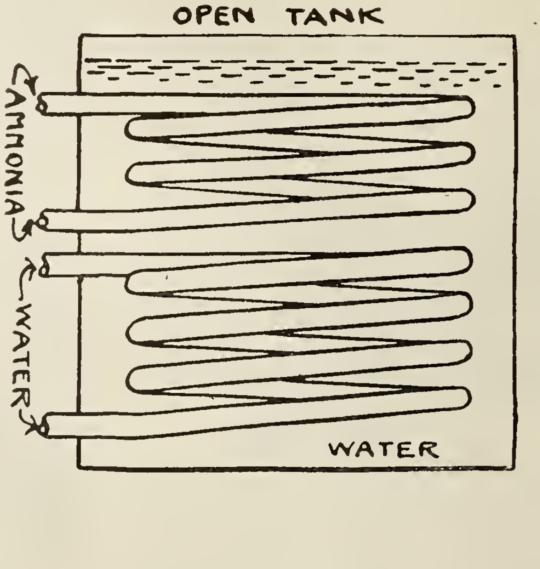

Fig. 2

REMOVING PIPE SCALE

I have read with interest recently various articles on the use of muriatic acid in removing scale from pipes, water jackets, etc.

It is perfectly true that under certain conditions muriatic acid will remove scale, especially when it is of a calcium-carbonate formation, since muriatic acid will combine chemically with this salt with the liberation of gas and the formation of a soluble salt, calcium chloride.

It must be borne in mind, however, that muriatic acid and other acids, which would have a like effect, are extremely powerful corrosive agents so far as iron, steel, brass, etc., are concerned, and even though extreme precautions are taken in employing it for removal of incrustation, the acid will exert its corrosive action on the metal in various places throughout the apparatus or lines to be treated. The acid, therefore, removes not only the incrustation, but also a certain amount of metal, depending on how long the metal is exposed to the action of the acid. The amount of metal removed is not such a serious factor unless the treatment is frequently employed, but it is a well-known fact that the corrosion that is started by acid has the ability to continue even after the original cause has been removed.

In other words, the use of powerful corrosive acids naturally starts up local seats of corrosion, which, while not evident to any appreciable extent at the completion of the acid treatment, are a source of future trouble unless extreme care is taken that every trace of acid be thoroughly removed by use of strong alkalies; even then there exists a possibility of future trouble due to the acid getting into small cracks and crevices, where it will continue its action.

The use of acid, therefore, for scale removal in expensive engine installations and pipe lines, is in my opinion poor practice. I remember that over twenty years ago certain engineers made a practice of putting hydrochloric, or as commonly termed "muriatic acid," directly into steam boilers for the purpose of clearing out the injector, piping, and the boilers themselves. Needless to state, this resulted disastrously in many instances.

The removal of scale from boilers, pipe lines, engine jackets, condensers, etc., can be accomplished efficiently and safely with certain treatments which have been developed after careful study and research, and therefore it is not necessary to resort to methods that involve the use of reagents having a powerful, destructive action on the metal.

ROBERT JONES.

BELT TRANSMISSION

A simple belt transmission rule that does not seem to be well known is this: "A single belt running one foot per minute will safely transmit one watt of electrical energy per inch of width of belt."

Thus, if a single leather belt one inch wide runs 5,000 per minute it will transmit 5,000 watts. If the belt is 10 in. wide it will transmit 50 000 watts at the same speed of 5,000 ft. per min.

5,000 watts is equal to 5 kilowatts.
50 000 watts is equal to 50 kilowatts.

Should it be desired to convert the watts into horsepower, multiply the number of kilowatts by 1.34. Or multiply the number of watts by .00134.

Thus, 5 Kw × 1.34 = 6.7 h.p. or 5,000 W. × .00134 = 6.7 h.p.

The above also applies to solid woven cotton belting of the same thickness as leather belting. For light double leather belts add 25 per cent. For heavy double leather belts add 60 per cent.

TWO CYCLE ENGINE

Below is a formula developed by the writer for fitting the average two-cycle engine.

Of course, formulas of this kind are not absolutely accurate but they fit most cases, and that is what we want, in any case, much depends upon the workmanship, age, tightness, looseness, etc. of the engine and its parts.

My formula is:—Multiply the bore of the cylinder in inches by itself, then by the length of stroke in inches, then by the number of revolutions per minute, then by the number of cylinders, and divide by 10,800. The result will be the horsepower of the engine.

Expressed algebraically the formula is:—

$$\frac{D^2 S R N}{10,800} = \text{H.P.}$$

where D = Dia. of cylinder in inches.
S = Length of stroke in inches.
R = Revolutions per minute.
N = Number of cylinders.

W. F. SCHAPHORST.

CARING FOR CATALOGS

It is usual for power plant engineers to collect countless catalogs on different types of equipment, and after giving them the once over, to lay them aside carelessly instead of having them properly filed for future reference.

Some time ago I called at a plant to make an inspection of a large engine. This engine was equipped with an automatic stop, and as I had never seen one of that particular make, I asked the engineer if he had an instruction book on this device. He replied that he did have one, but did not know just where it was, and I soon found out that he was in no way interested in the device, and knew absolutely nothing about it.

To me this made the risk a poor one, as the care an engine gets is of great consideration in insurance. In talking further with me the engineer said that he had found it practically impossible to keep track of catalogs, so I outlined for him a system I have used for several years with good results.

I first had some boxes of convenient size made of light wood, and divided into five compartments by tin slides, and in the compartments, which are numbered A, B, etc., I filed my catalogs. I then made up a list of what was in each division and pasted it on the front side of the box over the compartment. I also keep a book on my desk in which I have a duplicate list (as shown in the cut) of what is in each compartment. With this system I have a record of each catalog on hand and can readily find any one desired.

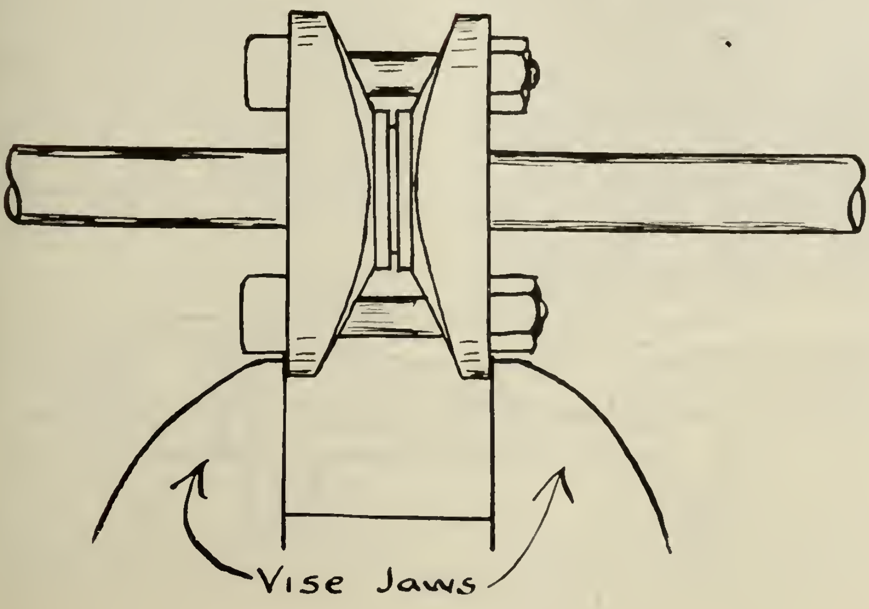
INSPECTOR.

REPLACING A BOLT

The sketch shows how I tightened a leaky joint in a liquid ammonia pipe line without first emptying the pipe to make the repair.

The lower bolt, shown in the sketch, was too short in the threads. That is, it was not threaded enough so that I could turn the nut on farther. Test with a sulphur candle showed the joint to be leaking on the lower side. I did not know what was the matter with the bolt at the time but I learned afterwards.

To replace the bolt I took a small vise off the bench and blocked it up under the pipe, as indicated, so that the jaws would just catch the flanges. I then tightened the vise jaws and relieved the bolt of its stress. I took off the nut from the bolt, removed the bolt and replaced it with another which was sufficiently threaded. The leak disappeared. The plant continued to operate without any hold-up.

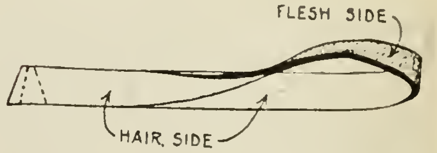


KINK IN CUTTING BELTS

Several years ago the writer was taught a valuable kink for cutting belts, as illustrated in the sketch herewith. This kink so far as I know has never before been published.

We are usually instructed, when cutting a belt, to use a square and make the cut "absolutely square" with the sides of the belt. However, if done in the manner illustrated here, it is not necessary to make the cut square. The important thing is to simply make the cut "straight."

This is done by giving the belt one turn as shown in the sketch and laying the ends one exactly over the other, both in perfect alignment. Then by making the cut "straight" even though not square with the sides, it will be found that the ends will make a perfect fit. The cut may make an angle of 45 degrees or even more with the sides. it makes no difference.



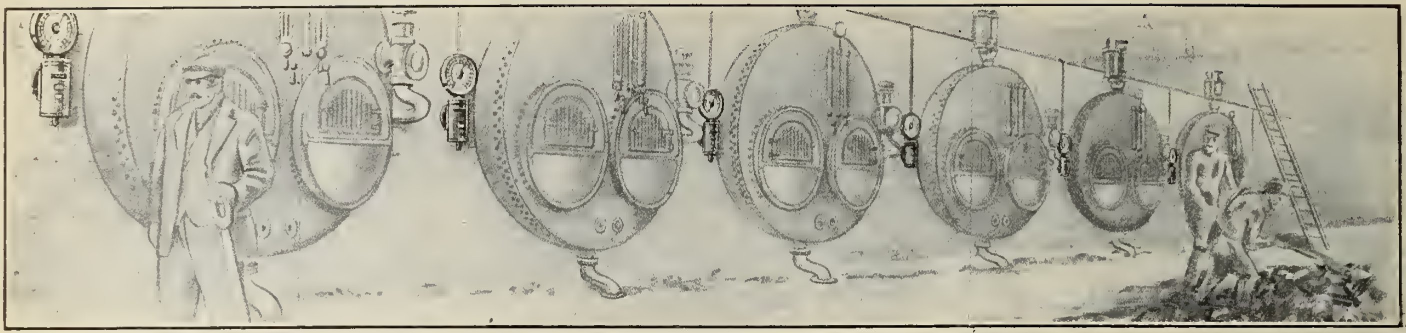
Of course, it is usually best to cut the belt square, or as nearly square as possible. By cutting it square, belting material is more likely to be saved than where the cut is made on an angle. But to be doubly sure, even if a square is used, it is a good plan to give the belt one turn as explained here and then if the square itself is not true, or if an error has been made in some way or other, the cut will automatically rectify itself.—W. F. SCHAPHORST, M.E.

The power plant at Redcliff, Alta., was struck by lightning and totally destroyed during a heavy storm on July 11. The damage is estimated at $15 000.

Harry Baker of the Provincial Hydro Commission is reported to have invented a listening device by which breaks in underground transmission lines can be located within six inches of the actual rupture.

The Underfeed Stoker Co. of Canada, Toronto, will supply stokers, and Goldie-McCulloch Co., Galt, Ont., will supply boilers, superheaters and economizers for the $58,300 addition to the power house at the University of Saskatchewan.

Gordon Perry, president of the English Electric Co., of Canada, leaves shortly for England, anticipating an absence of about six weeks largely on business connected with the company. His return may be followed by the announcement of a distinct broadening out of the activities of the company.



Easy Engineering Lessons in the Power House

By M. BARRY WATSON, B.A.Sc., M.E.,
Director of Engineering, Central Technical School, Toronto.

The Injector—How It Works—Why Steam Forces Water to Move Against a Pressure Equal to or Greater Than the Pressure of the Steam

PRACTICALLY all steam engineers have at some time used an injector to feed water into a boiler, using steam from the same boiler, or even at a lower pressure than the boiler into which the water was being forced. They all know that this result can be accomplished; but very few engineers know why steam will force water to move against a pressure equal to or even greater than the pressure of the steam.

Records show that as early as the year 1570 a crude type of injecting apparatus was used to pump water. The earliest patent office records respecting injectors show that in 1818 Mannoury d'Ectot patented a device somewhat similar to the modern injector. In 1857 Bourdon, after whom the modern pressure gauge is named, and in 1858 Giffard, patented various features in connection with injectors. The instrument as improved by Giffard was, however, the one to which various modifications have been made in the development of the modern types of injectors.

Behavior of Fluids

Before going into the action of the injector, it is necessary for us to understand something of the behavior of fluids in flowing through various shaped nozzles. When water is forced into a boiler by an injector, work is done which necessitates the expenditure of energy. The only source of available energy is the steam. Energy may be in various forms, of which the more common are heat, motion, pressure, electricity, etc.

Steam contains energy in the form of heat, and when in a high pressure boiler, it contains available pressure energy. Energy can be converted from one form to another, for example: If high pressure steam escapes to the atmosphere, its pressure energy is changed to velocity or kinetic energy, except for the little that is used up in friction in the orifice.

Must Move Faster

Let us imagine a pipe of the shape shown in Figure 1. If there is some fluid flowing through it, it is obvious that the same amount of fluid must pass through section B as passes through sections A or C; but since the area of the pipe is much smaller at B than at A or C, the fluid must move faster through B than through A or C. The faster a body is moving, the greater is its kinetic energy.

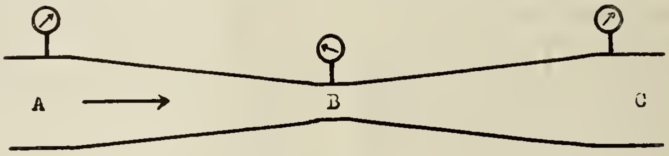


Figure I.

Therefore the kinetic energy, or the energy due to motion, of the fluid at B is greater than that at A or C. But the total energy at B can not be any greater than at A, because there is nothing to add energy to it, therefore, it must have less of some other form of energy at B than it has at A. On the other hand the kinetic energy at C is less than at B, therefore the fluid must have more of some other form of energy at C than at B.

The above deductions are borne out in practice. If we connect a water or steam pipe of this shape with pressure gauges as shown in Figure 1, we will find that when there is a flow through the pipe, the pressure at B is less than at either A or C. Thus we find out three things. 1st—That a fluid will flow from a low to a higher pressure under certain conditions. 2nd—That when a fluid flows through a converging nozzle, such as from A to B, Figure 1, the pressure decreases, but the velocity increases. 3rd—When a fluid flows through a diverging or expanding nozzle, such as from B to C, the pressure increases as the velocity decreases.

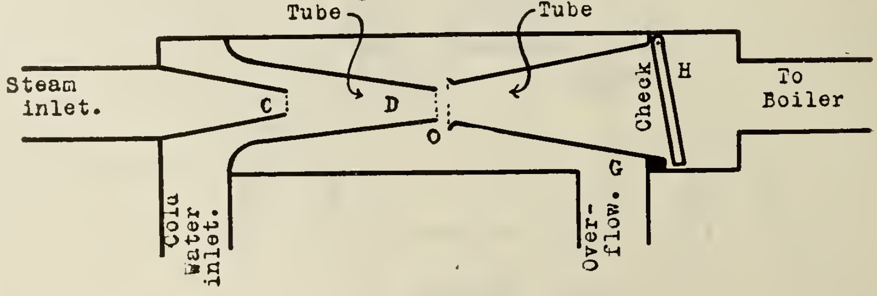

Figure II.

In its simplest form the injector is something the form shown in Figure 2. The action of the steam and water in it is as follows: High pressure steam from the boiler passes through the converging nozzle C where its pressure is reduced but its velocity increased. This steam passes on through the converging nozzle D where its pressure drops below atmospheric pressure. The steam can not open the check valve H because there is boiler water pressure behind the flap, so the steam escapes through O to the overflow G.

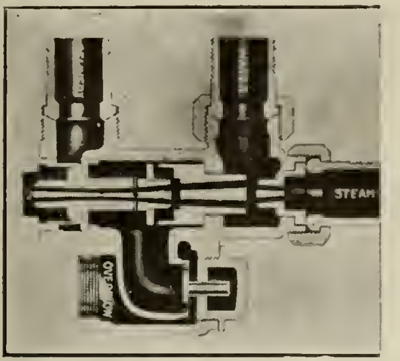

Figure 3.

The rapid flow of steam through D carries with it, or entrains, any air there may be in the cold water supply line, causing the pressure therein to drop below atmospheric. Water will then rise in the supply pipe until it comes in contact with the steam jet in the combining tube, as nozzle D is called; here it condenses the steam at the same time absorbing any energy it contained.

The kinetic energy that was in the steam is sufficient to give the water speed or velocity enough through the jet D, that it enters the delivery tube, which, being a diverging nozzle, causes an increase in the pressure of the water as the velocity decreases. This increase in pressure, as will be proven later, is more than sufficient to overcome the pressure of the boiler water on the back of the check valve, and the water passes through into the boiler.

High Vacuum at O

Because of the high vacuum at O. usually a vacuum up to 25 inches of mercury. air would be drawn in through the overflow G and forced into the boiler with the water. To prevent this action, the overflow is usually provided with a check valve, though sometimes a hand operated valve is used, which should be closed as soon as the water starts to come through the injector.

A modern type of automatic injector is shown in Figure 3, while Figure 4 shows a positive injector commonly known as the locomotive type.

To prove that the principles stated above will accomplish the stated object, it is necessary to study the relative amounts of energy imparted to the feed water by the steam, and required by the water in order to enter the boiler against pressure. Before going into this question, it may make the operation of the injector appear more simple if we consider the volumes of steam and water drawn from and put into the boiler by the injector.

As a general thing an injector will feed from 10 to 25 pounds of water into the boiler for every pound of steam used. Let us assume for sake of an example a large amount of water such as 20 pounds per pound of steam, because if we can prove that one pound of steam will put twenty pounds of water into the boiler, it is obvious that it will easily put in less than that amount. While inside the boiler the steam used and the water fed will be at the same pressure.

At 100 pounds pressure per square inch by the gauge the volume of one pound of steam is about 3.83 cubic feet. The volume of the water put into the boiler will be that of the 20 lbs. of water and the 1 lb. of condensed steam, which will make just over 1/3 of a cubic foot. Thus we see that the volume of steam taken out of the boiler is about 11½ times as much as the volume of the water put in. This looks as if there ought to be energy to spare, which we will find to be so.

Energy Used Up

Let us now consider the energy used in the injector. Consider one unit of mass, or weight, of steam. In a large steam supply pipe leading to the injector this unit mass of steam has large pressure energy and practically no kinetic energy. It has been found experimentally that steam issuing through a jet from 100 pounds per square inch gauge pressure has a velocity of 1,466 feet per second. The kinetic energy of the steam escaping through a steam nozzle is given by the formula $E = \frac{1}{2}MV^2$ when M is the mass or weight and V is the velocity of the steam in feet per second. Thus one unit mass of steam has energy equal to ½x1x1.466 = 1,074,578 foot pounds, or in round numbers says 1,075,000 foot pounds.

If this one unit weight of steam is condensed by and mixes with 20 units by weight of water, the total kinetic energy is transferred by impact to the mixture. By reversing the above formula we get

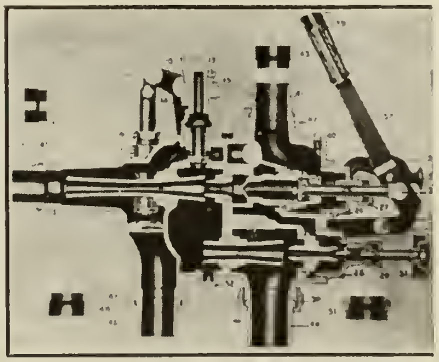

Figure 4.

$$V^2 = \frac{E}{\frac{1}{2}M} = \frac{2E}{M} \text{ or } V = \sqrt{\frac{2E}{M}}$$

Thus the velocity of the mixture at the end of the combining tube in the injector will be

$$V = \sqrt{\frac{2 \times 1{,}075{,}000}{21}} = \sqrt{102{,}381}$$

or about 320 feet per second. We shall now see how much pressure we could develop by passing this water through a diverging nozzle such as B-C in Figure 1 or the delivery tube in an injector.

Experiment has shown that the velocity of water in a jet is found by the formula $V = \sqrt{2gH}$, or $V = 12.03\sqrt{P}$, where V is the velocity in feet per second, and P is the pressure back of the jet in pounds per square inch. Reversing this formula we get

$$\sqrt{P} = \frac{V}{12.03}, \text{ or } P = \frac{V^2}{144.7}$$

Thus the pressure increase, if our jet keeps on expanding until the velocity is negligible, or all the kinetic energy is converted into pressure energy, will be

$$\frac{320^2}{144.7} = \frac{102{,}400}{144.7} = \text{about } 709,$$

or over 700 pounds per square inch. It is thus seen that the water moving with this velocity could be made to produce any pressure up to this limit. In practical injectors, however, the discharge nozzle is not expanded so large as to reduce the velocity to a negligible amount, but just enough to insure the pressure of the water being well above boiler pressure.

In closing, the author might answer a question which large numbers of engineers have asked him. "What is the difference between an inspirator and an injector?" The word "inspirator" is the trade-mark of the Hancock Co., who make injectors under this name.

Joseph E. Michaud, member of the provincial government of New Brunswick without portfolio, has been appointed a member of the New Brunswick Electric Power Commission.

The Quebec Power Co. directorate met in Montreal on July 13, to arrange final plans for taking over the Quebec Railway Light, Heat and Power Co.

W. R. Clubb, Minister of Public Works, Winnipeg, will receive tenders up to August 2, 1923, for the supplying and erecting of one water tube boiler at the power house, Hospital for Mental Diseases, Selkirk, Man.

George Kidd, general manager of the British Columbia Electric Railway Co., Vancouver, B. C., was appointed president of the company by the board of directors at a recent meeting in London, England. W. G. Murrin has been appointed vice-president, and A. T. Goward manager of the Vancouver Island System.

Rules for Routine Operation of Power Boilers

A.S.M.E. Sub-Committee Suggests Best Methods of Obtaining Maximum Efficiency at a Steam Pressure Exceeding 15 Lbs. Per Sq. In. Above Atmospheric Pressure

IN STARTING a new boiler or one that has been out of service for an extended period, see that the combustion chamber and gas passages are clean and in good repair. See that all clean-out doors are closed tight.

Operate and see that both inlet and outlet dampers are free and in good condition. Leave the back dampers open. Operate the stoker and draft fan to see that they are ready for service. Make sure that the grates are satisfactory and in place.

Examine the inside of the boiler and make sure that it is free from tools and foreign matter and that there is no one in the boiler; then close manhole openings.

See that blow-off valves, water column and water-glass drains, try cocks and feed valves are in good working condition and closed. Open vent valves.

By means of auxiliary feedwater connections, fill the boiler with water to a level a little above the surface blow-off and then close the auxiliary feed connections. Open and close try cocks and blow-down valves on water column and water glass in order to make sure that these connections are not stopped up.

Draw off water through surface and bottom blow-off valves until the level of the water in the boiler is at the bottom of the water glass and then raise the level of the water to a point about half inch below the normal water line by opening the stop valve in the main feed line.

Ease Up on Stem

Ease up on the stem of the main stop valve without lifting the valve off the seat in order to make sure that the valve is not stuck.

Open valves to steam pressure gage.

If coal is used as a fuel, cover the grate with a thin layer of coal and start a light fire. Where pulverized coal, gas or oil is used as a fuel, make sure that the back damper is wide open, create light draft, with fan if necessary, place torch or fire near burner to insure quick ignition and start light fire by admitting fuel slowly.

If the boilers use oil as a fuel and the system is new or has been out of service for a considerable period, first clean and examine the strainers and remove, clean and examine tips and burners. If compressed air is available, blow out the oil supply lines with air. Place and adjust burners and tips and work the air register to see that they are in good working condition. Close individual burner throttle valves.

Remove any spilled oil about burners, fronts and floor and see that there is no oil on the floor of the combustion chamber. Ventilate the boiler by opening draft gates and dampers.

If no steam is available for oil pump and burners, raise steam in boiler by wood fire. Remove any excess accumulation of water in oil tank. Have oil pumps warmed up ready for use. Open suction-line valves and pump oil to burners. If oil lines are equipped with air chambers, charge them with compressed air. Examine oil lines and equipment for leaks.

Light Center Burner

Light the center burner by holding hand torch near and just under tip or burner standing well clear to avoid possible flare back. If torch is snuffed out before oil is lighted shut off the oil and relight the torch. Always use the torch for lighting burners until the brickwork is intensely hot and even then if all burners are out. Next light the adjacent burners but be sure that there is an excess of draft before lighting additional burners. Do not permit the oil to impinge on the brickwork or parts of the boiler.

Enclosed find $2 subscription to Power House for one year. Mail the paper to Daniel Fenton, P. O. Box 271, Drumheller, Alta. Mr. Fenton is a friend of mine and I have shown him how much good he can get out of your paper, so he asked me to mail his subscription at once. I have been a subscriber for about eight years and I would not be without one now.

Gilbert D. Barchyn,
P. O. Box 209
Drumheller, Alta.

Test the steam coils in the heater for oil.

After starting a light fire and if the entire setting is new, the fire should continue until the brickwork is dried out thoroughly which in the average case takes several days; if the combustion chamber only has been renewed keep the fire going about 48 hours. After the usual week-end shut down, a light fire should be carried for about one hour. Only in extreme emergency should steam be raised in less than a half hour. Do not permit the fire to generate a steam pressure until about thirty minutes before cutting the boiler into the line.

In case of a new setting, ease up on buck stays and tie rods to allow for possible expansion of the brickwork. After water becomes heated, check the level of the water in the glass with try cocks and examine blow-offs for leaks. After steam has escaped through the vent valves for a few minutes, close the valves.

After brickwork is dried out and the boiler heated, begin raising the steam pressure slowly, especially in internally fired boilers where the circulation is sluggish. Keep the water level constant. When the steam pressure approaches the working pressure, examine the boiler for leaks, blow out the pressure gage connections and test the safety valve by hand. Blow down boiler to remove sediment.

Protect Before Lighting

If the boiler is equipped with a superheater of the indirectly fired type not constructed to withstand the intense heat during the firing up period, see that it is protected before lighting the fire by flooding or by closing dampers installed for the purpose.

Drain very thoroughly the steam connections between the boiler and the header or steam main. Where a non-return check valve or stop and check valve is not installed, the stop valve shall be opened very slowly and only when the pressure in the boiler is exactly the same as the pressure in the header. If the main stop valve has a by-pass, the by-pass should be used until the pressures are equalized. In any case the stop valve shall be opened very slowly and the operator should stand by for a few minutes after the stop valve has been opened wide; if any disturbance or hammer occurs in the boiler or in the pipe line, close the stop valve at once.

If a non-return check valve or stop and check valve, as the case may be, is installed, open the stop valve when the pressure in the boiler is 10 or 15 lb. less than the pressure in the header, and let the non-return check operate automatically.

Firing Boilers

Aside from the standpoint of economy, the fire should be maintained as uniformly as possible in order to avoid excess combustion, undesirable variations in temperature and possible gas explosions.

Fires should be cleaned at stated periods, if possible, and when boilers are operating at low rating as at noontime and just before peak loads. Avoid holes in fire and excessive draft while burning out the fire. Clean fires as rapidly as possible to minimize cold air in the boiler. Do not fire too heavily immediately after cleaning. Do not pile hot ashes and clinkers against boiler front, use care in quenching and remove ashes as soon as possible.

Do not bank fires any more than necessary. When fires are banked, make sure that a continuous light current of air is passed through the boiler. This is usually accomplished by having the ashpit doors closed, the firing doors slightly opened and the back damper perforated or nearly closed.

Handling Boilers

The most important rule in the safe operation of boilers is to keep water in the boiler and as constantly at the proper level as conditions will permit. Never depend upon automatic alarms or feedwater regulators. Any inattention, other duties or reliance upon automatic devices cannot be accepted as an excuse for a boiler damaged by low water level.

The first duty on entering the boiler room is to ascertain whether the valves and connections between the boiler and water column are free and open especially when starting up in the morning after the fires have been banked over night. Then blow down the water column, noting the return of the water in the glass, and try the gage cocks until sure of the water level. This should be done at the beginning and end of each shift and also several times during the shift. Have the water column well lighted and keep the water glass clean. Do not allow steam to leak from the water column or its connections, as this will cause the water glass to show a false level.

Try Gage Cocks

If the level of the water is not visible in the water glass, try the gage cocks to determine whether the level of the water is above or below the water glass. If the level is below the water glass, stop the supply of fuel immediately and then the supply of air; close the dampers and ashpit doors. Close the feedwater valve and under no circumstances feed water into the boiler. Haul the fire and, in the case of stokers or chain grates, keep them in motion with the fire doors open. Do not throw water on the fire with fire or other hose. Do not open the safety valve or change the steam outlet valves or make any changes that will cause a sudden change in the stresses acting upon the boiler. Examine the bottom blow-off valves and repair them if they are found defective. Find the cause of the failure of the supply of water.

If foaming occurs check the fuel supply and close the steam outlet valve long enough to determine the true level of the water in the glass. If the level of the water in the water glass is sufficiently high, blow down some of the water in the boiler and feed in fresh water. Use surface blow-off if any are installed. Repeat the alternate blowing-off and feeding several times, and if the foaming does not stop, draw the fire and continue the alternate blowing-off and feeding. When the boiler is sufficiently cooled off, empty the boiler and look for the cause of the foaming which may be caused by oil or other foreign matter in the feedwater or by scale solvent. Test safety valve and connections of water column and water glass for any choking or sticking. Determine positively the cause of foaming and adopt measures to prevent its recurrence.

Beware of Oil

Watch carefully for any signs of oil in the feedwater heaters, water glasses and blowdowns. If a boiler becomes coated with oil or grease, shut down the boiler and clean it thoroughly.

Execute carefully all instructions given for the treatment of feed water in your particular boiler room. Do not experiment with "home made" treatments or boiler compounds, unless advised to do so by a chemist experienced in feedwater treatment.

Except where the amount and frequency of blowing down is determined by chemical analysis, blow down at least one gage every twenty-four hours. The amount of blowdown depends upon the number of hours per day the boiler is in service, the rate at which it operates and the kind of feedwater used. Blow down the boilers at a period in the day when the circulation of water in the boiler is slowest. Always open the cock first and the valve second; in closing, close the valve first and the cock second.

Always open and close the blow-off valves carefully and slowly; if unusual effort is necessary to close the valve or cock, do not try to force them shut but empty the boiler and find the cause. In blowing down, open the cock or valve until it is half open and leave in that position until the water is blown down about half an inch in the water glass; then open the cock or valve wide open until the blowing off is completed. See that the valve shuts tight and remains tight. Repair all leaky blow-offs as soon as discovered. Use the surface blow-off frequently for a short period of time.

Lubricating oil used on the main and crankpin bearings will pick up minute particles of carbon if the engine is of the trunk piston design. This carbon will not settle out of the oil, and a first class filter or filter press is necessary. The loss in oil should be made up at least once a week and it should be remembered it does not pay to use cheap oil. All reputable oil companies have an oil suitable for Diesel engines and the engine builder is in a position to advise as to the best oil.

To Signal Operator

Where the water glass is not in view of operator blowing down a boiler, another operator shall be stationed where he can see the water glass and signal to the operator who is blowing down the boiler.

When small leaks occur, locate their source and repair them as soon as boiler can be removed from service. If a serious leak occurs such as a leak along the longitudinal seams, shut down the boiler immediately by gradually reducing the steam pressure and have the boiler examined by an authorized inspector.

Do not make any repairs upon a boiler, piping or auxiliaries while they are under steam pressure. Calking of pipes and joints and setting up of nuts and bolts under pressure to stop leakage must be prohibited.

Soot should be dusted from the tubes once a day; whether a lance or soot blower is used, drain the steam or air-supply connections so that the steam or air is practically dry. Never use steam for dusting off tubes when the boiler is not under pressure. When a boiler is to be shut down, dust the tubes before the fire has died out and with the draft on after the boiler has been cooled, brush or scrape any hardened soot or deposit from the tubes.

Remove ashes frequently and do not permit the accumulation of any large amount of ashes in the ash pit, boilers, flues or base of stacks. Do not pile ashes against the furnace front and, when wetting down ashes, make sure that no water is thrown upon hot castings. Do not leave ashes banked about blow-off pipes as a protection.

When ashes are removed by a suction system, an explosion door shall be provided on the storage hopper. Where steam-jet ash conveyors are used, see that all operators are warned against the water which may collect upon the top of the ashes in the hopper and may flow suddenly from the gate when the ashes are being removed. When necessary to bar through the gate to release clogged ashes, the operator shall be warned to stand sufficiently aside to avoid being burned by the hot ashes or water.

Care of Appliances

Test the safety valves at least once a day by gently raising the valve off the seat by hand, or, when practicable, test the valves daily by raising the steam pressure to the blowing pressure of the safety valve. If the valve sticks do not try to release it by hammering; drop the pressure in the boiler and clean the valve seat or correct any other defect that may be found. Repair or replace leaking safety valves as soon as discovered.

When a safety valve blows, note the pressure on the boiler steam gage and, if the stipulated blowing pressure varies more than 5 lb. from the pressure noted on the gage, test the gage. If the gage is found correct, adjust the safety valve.

Do not permit setting or adjustment of safety valves by any one but a competent person. Do not have the water in boiler above the highest gage cock when setting or adjusting the valve. When the spring becomes weak and must be screwed down to secure the stipulated blowing pressure, make sure that the spring is not screwed down so far that there is a restriction of the proper amount of opening of the valve.

Do not open the safety valve to reduce the pressure in the case of low water in the boiler.

Blowing Off Point

Never set the blowing point of a safety valve above the authorized pressure of the boiler.

When making a hydrostatic test do not try to hold the safety valve closed by screwing down the spring; blank the valve, clamp the seat in place or use some other suitable method. Make sure that the safety valve is placed in good working condition after the hydrostatic test has been made.

Keep scale, dirt or other foreign matter from collecting between the coils of the spring. When running a wire in the drain hole in the escape pipe to ascertain if it is clear, be careful that the wire does not move scale that may fall over the drain opening when the wire is removed.

Blow down the gage connections frequently and especially when checking the safety valve, raising steam in a boiler and when foaming occurs.

Broken Water Glass

When a water glass has broken, remove the broken pieces and, with head turned away from the water column, slowly open the bottom valve to blow out any remaining pieces. Before inserting the new glass, see that the glass is of the exact length required and that the connections are in line. Insert the glass and set up the stuffing-box nuts, taking care not to set them up too tight. Then warm the glass by opening the drain cock of the glass and with head turned aside, open the top valve slightly and let a small current of steam flow through the glass. Close the drain cock after the glass is sufficiently warmed, open the bottom valve slightly and when the level of the water in the glass has become stable, open the bottom valve wide and then open the top valve wide, all the while keeping the face turned to one side.

Water glasses must be kept clean. Do not clean a glass with waste or linty cloth; use cloth, free from lint and dirt, wound about a wooden stick. Do not use a metal rod that would scratch the glass and start a crack.

Boilers Out of Service

To cut out a boiler, first cut off the supply of fuel. In a coal-fired boiler close ashpit and fire doors and close dampers. In an oil-fired boiler, continue the air supply until any oil on the floor of the combustion chamber is consumed and the gas passages are well ventilated; then close dampers. After the boiler ceases to require feed water and the non-return check valve, if any, on the steam line has closed, close the main steam stop valve. When possible blow-off the tubes before the fire has died out. Fill the boiler to three-fourths of a glass.

After the fires have died out, close all doors and open dampers. When the pressure has dropped to blowing down pressure clean the furnace of all coal and ashes and permit the brickwork to cool for not less than two hours. When there is much sediment in the boiler, longer time must be allowed.

After cooling off the setting, open the blow-off valves when the pressure in the boiler has been reduced to about 10 lb. if it is not feasible to empty the boiler at atmospheric pressure. When the boiler to be emptied is set in a battery, make sure the blow-off valves that are opened are on the boiler which is to be emptied. As soon as the boiler is empty, remove the manhole plates and covers of other openings.

Examine Boiler Often

Examine boiler frequently to determine how often the boiler should be washed. Wash more frequently when the boiler runs longer hours per day or at higher ratings, when feed water becomes foul or when scale solvents throw down scale.

Remove manhole and handhole plates, close feed valves, steam outlet valves and blow-off valves and hang sign on boiler to indicate that a man is working inside.

Use hose with considerable force or hand tools, if necessary, to remove scale. Disconnect blow-off pipe close to the boiler and run water to waste. Horizontal-tubular boilers should be washed from below as well as from above. See that the water does not get on the brickwork of the combustion chamber.

Pass Light Inside

After washing the boiler pass a light inside and see that the cleaning has been thorough and that no tools are left inside. If the boiler has been treated with kerosene in the feed water, ventilate the boiler; do not use a naked flame to examine the boiler.

Do not remove scale with kerosene if it can be done by any other means. If it is used, see that the boiler is dry and cool. Do not use kerosene in large quantities in a room where other boilers are in service unless special precautions are taken to keep the vapors from escaping into the boiler-room. Keep all lights away from the boiler except incandescent lamps enclosed in moisture-proof globes and guards.

Spray the inside of the boiler and, after allowing it to stand a sufficient length of time, wash thoroughly with hose and copious amount of water. Do not enter the boiler until it has been thoroughly ventilated. Also ventilate the boiler before entering it the next time that it is opened.

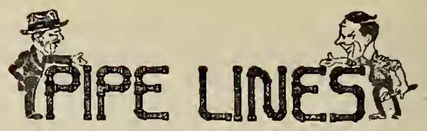
When boiler has been allowed to become heavily scaled or coated with oil it may be cleaned by boiling out with soda ash and kerosene. Fill boiler well above water line with water containing 50 lb. of soda ash and 5 gallons of kerosene to 1000 gallons of water. Close the boiler and start light fire sufficient to carry about 5 lb. pressure in the boiler. Continue boiling for two or three days, empty the boiler, then wash thoroughly and ventilate the boiler. Use the usual precaution against oil and vapors.

Personals

The Dominion Power & Transmission Co., Terminal Sta., Hamilton, has purchased additional power from the Canadian Niagara Power Co., to supplement its own supply from Decew Falls, and plans to install machinery and equipment for changing 25-cycle current to 60-cycle, at Niagara Falls, Ont.

F. W. James, manager of the Union Natural Gas Co., Chatham, Ont., is resigning and his place will be taken by S. A. Morse, at present secretary of the company. R. W. Bevan, formerly of the Canadian Western Natural Gas Co., Calgary, is now associated with the Union Company as superintendent of production.

The Bancroft Light, Heat & Power Co., Bancroft, Ont., is having plans prepared for the development of 2,500 h.p., about 50 ft. head, equipment to include turbines, generators, oil switches, circuit breakers, lightning arresters, insulators, panels, cranes, gates, racks, etc., at High Falls. The cost is estimated at $300,000.



PIPE LINES

No longer little Micky Hare,
Whose ways are mild and meek,
Will keep my clothing in repair
For 50 cents a week.
He now demands a larger sum
Which I esteem too dear
For lately Michael has become
A Pressing Engineer.

* * *

A slight adjustment of speed in a shunt or compound-wound motor may be accomplished by shifting the brushes; movement in a direction against the rotation causes an increase of speed, and *vice versa*. Too great a movement may interfere with good commutation. A greater increase in speed may be accomplished by weakening the field or by increasing the air gap by removing shims under the polepieces.

* * *

The days when Tonio Dorio
Would clip and trim my lawn,
And make my kitchen garden grow,
For ten a month are gone.
He now is making wads of pelf
Takes contracts by the year,
And on his billheads styles himself
A Mowing Engineer.

* * *

A governor is said to be stable when it assumes a definite position for each particular speed and when a change of speed is necessary for a change of position, while a governor which is in equilibrium at but one speed is said to be isochronous. Perfect isochronism would be impractical as the slightest increase in speed above the normal would result in cutting off the steam, accompanied by a sudden decrease of speed, following which the steam valve would open wide thus giving rise to extreme fluctuations.

* * *

The lads from Greece who cleaned my shoes,
Once in a cheaper time,
Now with haughty scowl refuse
My little proffered dime.
One sees them by appointment now,
They're risen, it appears,
And have become, so they avow,
Shoe Surface Engineers.

* * *

Every direct-current generator of regular construction may be operated as a motor, and *vice versa*. The only essential difference is in the controlling apparatus. When used as a dynamo, the machine is provided with a high-resistance rheostat connected in series with the shunt-field windings and when used as a motor it is provided with a low-resistance starting rheostat connected in series with the armature. When run as a dynamo, however, the speed must be somewhat higher than when run as a motor, if the voltage remains the same in both cases; this is due to the voltage drop through the armature circuit.

News Editor

The Sting of "The Puff"

"ONE reason I'm now strong for Power House," said a stoker manufacturer in Toronto last week, "is because the paper no longer gives 'puffs' and over-done write-ups. Its pages are filled with news, ideas and real information of value to the engineer."

That statement merits thought as to the real nature of a "puff"—that relic of the old patent medicine days—when a reader read about a marvelous case which was finally cured with a bottle of Billsby's Bilious Bitters, and when the reader had read to the end, shouted "stung," and threw the paper at the cat.

In Power House to-day advertising is recognized as advertising and editorial matter as editorial matter. And there is a written law that never the two shall be mixed.

Nobody now pays attention to puffs. No, nobody except those who are puffed, and even they don't believe what the puffers say.

The pages of Power House are always wide open for news, ideas, information, anything that will help engineers to cut operating costs with the minimum of labor. Instead of "puffs," which at best had little meaning and still less value, we can all help ourselves by helping to gather really practical ideas in power plant economy.

What everybody is interested in is what engineers are doing, how they are doing it, and what the results are.

High Pressure Steam Values

THE value of steam as a means of transforming heat into work lies, as every Canadian engineer knows, in the comparatively large amount of heat energy which can be transferred from the furnace to the engine by every pound of the working fluid, without involving pressures or temperatures beyond the resistance of ordinary materials.

Practical considerations for many years limited steam pressures to about 200 lb. per sq. in. but with the development of manufacturing methods, a decided tendency is now evident to operate boilers at much higher pressures, indeed, a steam pressure of 350 lbs. per sq. in. is not regarded to-day as exceptionally high.

There are two reasons for this tendency to increase pressures. One is the desire to secure greater thermodynamic efficiency, and the other is the appreciation of the practical benefits of the reduction in the size of steam pipes which high pressures render possible.

The latter reason is of considerable importance, for when a single turbo-generator may require as much as 150 tons of steam an hour, the less the volume of the steam, so long as boiler drums, pipes and joints will stand up, the better.

High pressure generation of steam is bound to give rise to problems in boiler construction and maintenance which may not be easy to solve, and the question obviously arises as to what compensating advantages in efficiency may be hoped for.

The value of a pound of steam is, of course, by no means proportional to its pressure, but only to the amount of heat which can be transformed into work by expansion to some lower pressure.

Taking 0.5 lb. absolute or a vacuum of about 29 in. as the lowest practical exhaust pressure, a pound of dry steam at 500 lb. pressure, if used in a perfect engine, will only do 15 per cent. more work than the same weight of steam at 200 lb. pressure. The proportion of the heat supplied to the steam, which can theoretically be turned into work, is 35.3 per cent. in the former case and 31.96 per cent. in the latter so that the gain, either in work or efficiency due to the higher pressure, is not very great.

If we push the initial pressure still higher, say to 2,400 lb. per sq. in., much the same result is obtained. The available work per pound, calculated from Professor Callendar's tables, is 261.16 pound-centigrade units, or only 27.05 per cent. more than in a pound of steam at 200 lb. pressure, and the thermodynamic efficiency of a perfect engine using steam even at this extremely high pressure would not exceed 41.78 per cent.

In practice, of course, greater efficiency is sought by superheating steam to the highest temperature which practical considerations permit, at present, about 700 deg. Fahr. In order to take advantage of the Centigrade scale we will assume an upper limit of temperature of 380 deg. C., the equivalent of 716 deg. Fahr. With steam at this temperature, at 200 lbs. pressure, in a perfect engine exhausting 0.5 lb. absolute, the available heat will be 251.53 units, which is 33.82 per cent. of the total heat supplied to the engine.

At an initial pressure of 500 lb. the available heat will be 276.58 units, or 37.6 per cent. of the total, and at a pressure of 2,400 lb. the corresponding figures are 295.78 units, or but 43.28 per cent. of the total.

These figures are sufficient to show how slowly the value of steam increases with its pressure, whether superheated or not. Nevertheless every increase in efficiency, however small, is worth obtaining, if it is not counterbalanced by corresponding disadvantages.

The Structure of Society

THE foundation upon which the structure of society is built is as old as society itself. This foundation is confidence. Customs, manners, and usages may change with the centuries, but confidence must endure lest the superstructure tumble. The world views differently from generation to generation the life and the interrelations of men, and draws different conclusions. Laws change as conditions change, and methods of life are constantly changing.

Man of to-day is born with the same instincts, with the same nature as man of a thousand years ago. He has, however, learned to restrain his instincts; to treat his fellows with more respect and consideration; to have confidence in his neighbor; and not to look upon society as a natural enemy.

Confidence is a state of mind or a firm belief in the trustworthiness of others. It manifests itself in our actions; in our behavior towards one another; and in the most common and homely affairs of every day. An executive has confidence in his engineer, his lawyer, his banker; and this confidence is an expression of the development of human nature brought about by education and necessity.

There will alway be pessimists as there always have been. They will tell you that the world has not changed for the better, and that there is no more honesty to-day than in the time of Alexander, Charlemagne, or Napoleon. These are the people who contend that every man has his price. Having no confidence in themselves, they have none in any one or any thing.

Electricity in the Power House

TRANSFORMER TESTS

IF THE utmost service is to be obtained from any transformer it is essential to conduct certain tests at regular intervals and also to make thorough periodic inspections of all the parts comprising the complete apparatus.

Contrary to what might at first be thought, it is infinitely more important to make thorough inspection of all the parts, rectifying any defects which might be found, than to subject the apparatus to certain tests, though these undoubtedly have their value. Tests that can be made on site are usually somewhat limited in extent on account of the lack of suitable testing plant and pressure and current, and only in large power stations and the like can complete tests be made which would be comparable with routine factory tests.

In the average power plant, however, it is not necessary to make anything like the exhaustive tests on site that are conducted in the factory on a new transformer, and the reasons are fairly obvious. For instance, it is unnecessary to test for losses, as any abnormal increase would be indicated by thermometer readings or by contact of the hand with the top of the tank.

Presence of Smoke

A short-circuit between turns of either windings would make itself known by the presence of smoke issuing from the tank and by the tripping of the supply switch, so that over-potential pressure tests are not necessary. Ratio and impedance will not vary, and the no-load current will not increase unless a fault occurs in the magnetic circuit, which would increase the iron loss and, therefore, the temperature rise. Pressure tests to earth should not be indulged in, as, if the transformer is working satisfactorily, such tests only uselessly place excessive dielectric stresses upon the winding insulation. The tests which may advantageously be carried out are:

(a) For the presence of moisture in the oil.

(b) For the presence of acid in the oil.

(c) For the presence of sludge deposits in the oil.

(d) Megger tests to earth on insulated bolts passing through the laminated core structure.

(e) Megger tests of any insulated core clamping structure.

(f) Megger tests to earth of both H. T. and L. T. windings and between windings.

(a) The dielectric pressure test is by far the surest and most delicate test for the detection of the presence of moisture in oil, and this simply consists of applying a gradually increasing electrical pressure across a fixed gap between suitably-shaped electrodes. The electrodes should consist of ½-in. diam. polished metal spheres, set 0.15 in. apart, and they should be mounted in a glass container, for receiving the oil to be tested. The container should be chemically clean and dry before the oil is poured into it, as otherwise fictitious results will be obtained.

Disperse Air Bubbles

After the oil has been poured into the container all air bubbles should be allowed to disperse before pressure is applied across the gap. Electrical pressure is then applied across the gap, say, at about 5,000 volts to commence with, and if breakdown through the oil immediately occurs, moisture is certainly present. If breakdown does not immediately take place, the pressure should be raised gradually until preliminary sparking takes place across the gap and a clean breakdown occurs. Preliminary sparking indicates either the presence of moisture or of fibres in the oil and the determination of which of these is present must be left to the experienced judgment of the engineer in charge.

Several tests should be made on different samples, so as to obtain a reasonable average figure. Each sample should be subjected to one definite breakdown only, and if this is appreciably less than 20,000 volts, the question of drying the oil should seriously be considered. The oil should, of course, be drawn from the bottom of the transformer tank.

It may happen, however, that the necessary testing apparatus is not available, in which case rough-and-ready approximate indications only must be relied upon. Perhaps the best known of these is to plunge an iron wire, heated to a temperature just below red heat, into the oil sample. If the oil be dry, a puff of smoke only will be the result, but, if it is wet, a characteristic crackling sound will be heard. Alternately, a sample of the oil may be heated in a test tube, when, if moisture be present, crackling will be heard. A third method is to pour some of the oil, which has been dried out, into a test tube containing anhydrous copper sulphate, shaking the two up together. If moisture is present in the oil the anhydrous copper sulphate will, to a certain extent, regain its characteristic blue colouring.

Tests for Acidity

(b) Rough tests for acidity may be made by shaking up a sample of the oil in a test tube with a piece of blue litmus paper. If this turns red, acid is present, and the rate at which the colour change takes place gives a qualitative idea of the acid contents.

(c) For this test it is only necessary to filter a sample of the oil and note the deposit upon the filter paper. Unless this is heavy it should not be necessary to filter the oil, and in any case a better indication can doubtless be obtained from an examination of the surfaces of the coils and core structure.

(d) In the larger sizes of circular core type transformers insulated bolts pass through the laminations for the purpose of securing them to prevent vibration. If the insulation on two or more of these breaks down to the core, large circulating currents may be produced in the bolts, and these may cause such intense heating as to distort the core structure and destroy the coil insulation. Before the coils are assembled in the shops upon the cores, these bolts are all pressure-tested to the cores at about 1,500 volts. The bolts through the yokes are treated the same. Megger tests on site will, however, give a clear indication regarding the qualitative condition of the insulation of the bolts, but it should be remembered that the top and bottom yoke bolts only are accessible, as the core bolts are obscured by the coils. If megger tests indicate a breakdown of any bolt insulation the fault should be repaired immediately.

(e) Core and yoke-end plates are usually insulated from the main magnetic circuit, so as to prevent the circulation therein of eddy currents resulting from straying flux. Similarly, coil-clamping structures, provided for taking up coil shrinkage, are also insulated and pressure-tested in the shops at about 1,500 volts. Megger tests should also be applied to these parts and any fault found should be remedied.

The Testing Megger

(f) Megger tests on transformer windings do not necessarily give a true indication of the exact electrical condition of the insulation to earth or between windings, as the case may be. This will be evident when one considers the relative pressures of the testing megger, and that for which the windings are perhaps designed, and no one would expect to be able to determine the true condition of insulation proportioned for a pressure of 20,000 volts, or even for 3,000 volts, by means of a 500-volt testing set. A 500-volt megger will, however, indicate whether the insulation is intact or not, and this fact, taken in conjunction with a knowledge of the immediately preceding operating

Oil Engine Efficiency Factors in Power Plants

By E. W. BERRY

Notes and Comments on the Selection, Maintenance and Care of Various Classes of Oil Engines for Different Classes of Service in the Power Plant

TO REALIZE the maximum efficiency in oil engine power plant operation, the plant must be properly designed, and the type of engines installed adapted to the class of service they are to be used in.

For instance, oil engine alternator sets supplying power to a cyanide mill or to a concentrator are at all times under peak load, a class of service that lends itself nicely to surface-ignition oil engine installations comprising either two or more sets or one full-power unit.

In the case of fluctuating loads, such as tram lines or large hoists, where the power demand from the one machine reaches from 50% to 60% of the total power of the engine, Diesel motors adapt themselves to that class of service ahead of all other types, because there is no danger of a cylinder going cold on off-peak load and ignition failing, as is the case in multi-cylinder surface-ignition oil engines when the strictest attention is not paid by the engineer.

In the case of municipal lighting and power plants where the difference between off-peak and full peak loading is greater than 30%, a series of power units of like size and type should be installed. In the case, for example, of a plant developing 1.200 k.w at full peak load with the power demand at off-peak being between 650 and 750 k.w., the most efficient installation would be three 450 k.w. units, the plant being laid out for unit installation to care for increased power demands at some future time.

Year-Round Efficiency

It has been found that the greatest all-year-round efficiency is attained by the use of small units in any class of work, and every time the unit size is divided the factor of safety increases 100 per cent. An illustration of the efficiency lost by using a single full-powered unit on some classes of work can be found in a plant the writer visited, where there was a single unit of 300 b.h.p. furnishing power to mine and mill. At the time of my visit the mill was shut down for repairs, and it was found necessary to pump water in all tanks; the pump required only 12 h.p., yet it was necessary to run the 300 h.p. engine for forty-eight hours to furnish that power.

Engines should be grouped as closely as convenient for accessibility. By so grouping it is possible to have a convenient upper runway connecting the valve decks of all units, and the switchboard should be so located that the synchronoscope can be seen from the control station of the incoming Diesel-alternator.

If the crank-pits of the A-frame engine or the crank case of the box-frame type be piped with conduit and wired for electric lights with a carbon filament lamp in each crank-pit it will greatly aid inspection, and the engineer can keep close watch on the condition of the bearings and lubrication. A good overhead crane system should be incorporated in each installation, wtih a capacity equal to the weight of the heaviest part in the engines and its travel should cover all units.

An Important Factor

A very important factor in the successful operation of semi-Diesels is the close regulation of cooling water. On light loads the best efficiency will be had by raising the temperature of the heads by cutting down the flow of the cooling medium. If the flow be allowed to continue after the load drops on a multi-cylinder surface ignition engine, one or two of the cylinders will cool down and ignition will cease for a few revolutions. If the load should come on while that cylinder is cool the governor will give the injectors full stroke, and when the dead cylinders resume firing the heads are apt to crack or other damage be done which can all be avoided by close attention to the regulation of the water.

In the first Diesel engine patented, air was not used to inject the fuel charge. This idea was a later development. It appears that compressed air serves to atomize the fuel particles in a very perfect manner. Outside of the chilling effect no better means can be found to act as the injecting agent. The air pressure carried depends upon the load on the engine, the character of the oil fuel and the design of the atomizer discs and cone.

In engines of the crank case compression type the oil drain compression by-pass should be adjusted so that sufficient air is compressed for complete scavenging of the burnt gases but enough air should be by-passed so the oil will not be forced from out the bearings. The by-pass will carry the used oil to the drain where it can be collected and purified. Care must be taken to see that the by-pass does not become stopped up with falling carbon particles, because then the used oil would collect in the crank pit and be thrown into the cylinder with the scavenging air, causing a run-away and possibly a wreck.

Fuel of 27 deg. Beaumé and above is recommended by the majority of surface-ignition engine builders, but the writer has achieved wonderful results from 24-plus oils. By keeping the engine well adjusted even heavier oil may be used successfully. Heavy fuels necessitate scraping the exhaust ports and cleaning the muffler pots at frequent intervals. On full load plants this should be done every week, though it will depend on the gravity of fuel used and on the load.

Gets Accurate Results

In plants that have no indicator the "time interval by ear method" of adjusting will give fairly accurate results. First with light load (10 per cent. or 15 per cent.) adjust the engine for speed, getting all cylinders as nearly alike as possible. When speed is adjusted, on a four-cylinder engine hang up all injectors and drop back two of them at once, noting mentally the time until these two cylinders have the engine up to speed. Then hang them up and drop the other two, noting time as with the other pair. If both pairs are fairly even, leave one pair hung up and cut in first one cylinder and then the other of the pair that is down. If the time interval between that pair is noticeable, very carefully adjust the slow cylinder until the time interval is no longer noticeable. Then hang that pair up and repeat the operation with the next pair. After adjusting this pair, break pairs. and repeat the operation then under full load test for speed. The torches should be burning slowly during the adjustments to keep the cylinders from going cold. Fairly accurate results may be obtained by this method.

A change from one grade of fuel to another will cause a very noticeable variation in speed with semi-Diesel engines. On a 200 h.p. engine the writer was using 27 plus oil when he received a car of gas oil, the effect of which was an increase in speed of seven revolutions.

Care Must be Taken

In shutting down surface-ignition oil engines care must be taken in closing off the cooling water. If allowed to flow at full amount, it will cool the heads down too rapidly, causing shrinkage stresses to be set up which may allow water to enter the combustion chambers. If the water be cut off immediately the jackets will become very hot, the effect of which will be the precipitation of the lime and salts in the water; the lime depositing on the heated surface of the combustion head and in time causing cracked heads. The best method is to allow a small flow of water through the jackets until the engine has cooled down slightly, and then the flow may be completely stopped.

In power plants where surface-ignition oil engines of the water-injection, or water-drip, type are used, care must be taken in ordering fuel oils. This type of engine is very susceptible to sulphur. If the sulphur content of the fuel be very high, with the water-drip type a series of events will occur as follows: the sulphur injected with the fuel in the form of SO will upon combustion of the oil change into sulphur dioxide gas—SO_2—which, being thoroughly mixed by the turbulence of the burning gases with the H_2O from the water drip, will form H_2SO_4—which immediately attacks the cylinder walls, exhaust passages, etc.

To Obtain Efficiency

To obtain full efficiency from the fuel, the water-drip must be closely adjusted so that under full load a light bluish smoke is obtained instead of a black smoke, which indicates insufficient water feed.

On surface ignition engines of the direct-injection type attention should be paid to the condition of the fuel nozzles, because the economy and efficiency of the engine will be governed by their condition. The nozzles should be removed at frequent intervals, taken apart and cleaned. Inspect carefully the conditions of the check ball, and, if it shows acid pits or is ringed by continued operation in one place, discard it at once. Never attempt to smooth a ball, as it is impossible to keep a worked-over ball from dribbling: If the seat be pitted it may be smoothed by grinding with clover leaf compound on the end of a stick the same size as the ball seat. Care must be taken not to enlarge the seat. If the ball should not seat, the nozzle will dribble and fuel will be wasted. This condition makes itself known by knocks in the cylinder, and unburnt fuel oil will be forced out of the ports, the exhaust from that cylinder showing darker than the others. This condition also causes muffler pot fires.

Low Gravity Oils

Diesel-motors show even better efficiency using low gravity fuel oils than with the lighter gravity fuels, because the heavy fuels burn more slowly, giving more gradual expansion. Less work is required to keep the fuel pumps packed when using heavy oil, though a higher injection pressure is needed for atomization.

The motors should be "indicated" at regular intervals, and any adjustments made that the diagram shows necessary. A diagram book should be kept in which all cards should be entered with full record of conditions indicated. An engine should not be operated with one cylinder showing low compression, but should be immediately shut down and investigated, because trouble may result if the piston rings are stuck with carbon, a piston in this condition scoring the cylinder very rapidly if operated for any length of time.

Lubricate With Care

The multi-stage compressor of atomized-injection motors should receive a large share of attention because it is the heart of the engine, and a very small trouble in it, if overlooked, will develop into a serious breakdown in very little time. This important part should receive careful lubrication with the best quality oil.

An analysis of the cooling water should be made by a competent chemist, and if lime or other scale-forming matter is found a closed system should be used and the water in the system treated with soda-ash or compound. Scale is very troublesome in Diesels, because very little of it forming in the water jackets of the compressor will cause the compressor to overheat, and when precipitated on the power-cylinder heads it will cause faulty heat transfer, ultimately resulting in cracked heads, burnt pistons and scored cylinders.

A 3,600 b.h.p. plant the writer visited used impure water with a straight cooling system. The result was the burning-up of two compressor cylinders and numerous cracked heads on the 1,000 h.p. engines. Upon the installation of a closed circulating system all trouble ceased.

Analyze Scale Samples

In case the engine is badly scaled before being noticed, samples of the scale should be analysed and the cooling water treated with a dilute muriatic acid, compound or soda-ash, as the analysis shows best. A simple field test the chief engineer can make at the plant to get an idea of the scale-forming matter in the cooling water is to take a test tube or water glass and fill nearly to the top with the water to be tested, adding a few drops of ammonia to make the water alkaline and a small amount of phosphate of soda to change the lime, magnesia, etc., into phosphates, which will precipitate and settle to the bottom of the test tube. The amount precipitated will give an idea of the amount of scale-forming matter in the water.

Lubrication of the motors is one of the most important factors in the operation of the plant. The very best oil should be used. It is false economy to use an inferior grade of oil on machinery of any class, and especially on oil engines. By using a good grade of oil, the proper amount, and running the used oil through a purifier very efficient service at a low cost per h.p.hr. will be obtained. It is very nearly impossible to get a gravity filter to clarify the oils properly.

The chief engineer should open up the motors and make an inspection of all parts at regular intervals, making all necessary adjustments, a record of which should be entered in the log book. If any part needing attention is noticed during routine attendance and cannot be adjusted while running, the engineer on throttle watch should make an entry of it in the log for the attention of the chief engineer, so the trouble may be attended to at the first shut-down.

Records of Operation

Complete records of the plant operation should be kept at all times, indicator cards filed with full data of conditions, humidity and temperature records, and a complete record of repairs, adjustments, fuel used, lubricating oil and running time should be entered in the engine-room log book. The chief engineer should plot a monthly and yearly graph from this data. A record of this type will give a check on the monthly and yearly operating efficiency of the plant.

It goes without saying that the deciding factor in the efficiency of the plant is the attendance. A very poor plant will show good results if the engineers know their business, and the best of installations will show poor results if the engineer and crew are inefficient. The most inefficient plants I have visited have been in charge of chief engineers that got the job through pull or politics and are afraid to hire engineers that know their business, for fear they will have their jobs taken away from them.

Their excuse is that they wish to train their own engineers from oilers at the plant. It is the greatest tribute to the Diesels that they run in spite of such inefficient attendance. This type of man is rapidly disappearing, because the power companies are beginning to realize that the engineer who insists on blaming everything that happens as a fault of the engine does not know his business, because hundreds of plants of all types of oil engines are developing full power, year after year.

Power Notes

The Border Cities Hydro Utilities Association, including the Windsor and Walkerville Hydro Commission employees, will hold the annual picnic at Sea Cliff Park, on July 26.

The Hydro-Electric Power Commission have decided to double the capacity of the power station at Acton, Ont., by the installation of three new 100 h.p. transformers.

A report made to the Hydro Commission recently states that in extending power to rural parts of Ontario, 650 miles of transmission lines have been laid. This makes power available in 93 townships.

The Dominion Engineering Works, Ltd., Montreal, have under construction two 58,000 h.p. turbines for the Queenston-Niagara development of the Hydro-Electric Power Commission of Ontario. The same company are also constructing two Johnston penstock valves and two sets of I. P. Morris governors.

Every-day Problems With Answers

Queries are invited on the every-day problems of all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped to solve a problem and a pleasure for us to pass on the data.

B. C. EXAMINATIONS

To whom should I write for information regarding examinations for British Columbia?—WALTER W. P. SINCLAIR, Medicine Hat.

Answer:—You should get in touch with the Chief Boiler Inspector, Department of Public Works, Victoria, B. C.

WANTS INFORMATION

If the cylinder rings of a steam engine become worn and have a slack fit in the cylinder, is it advisable to place on a smooth surface and tap with a cross peen hammer going all around the inside of the ring, in an endeavor to make it fit the cylinder tight again. If the job is properly done will the spring stay in the ring, and does it fit the cylinder correctly all the way around?

I have tried this several times but the rings soon become slack again after the engine has run but a short time, spots 3 or 4 inches long appearing on the rings, where there seems to be no rubbing against the cylinder walls.

I would like any engineers, who have had any experience in this matter or who can give me some advice on the matter to do so through the question box of Power House.—JOHN T. WOOLMAN, Espanola, Ont.

COMPRESSOR "RUN UNDER"

Should a horizontal motor-driven ammonia compressor be run under or over?
WINNIPEG READER.

In order that the pressure from the crosshead on the guides may be downward, a horizontal motor-driven compressor should be run under. In the case of a compressor the crosshead is driven by the crank, which is the reverse of the condition with an engine, where to bring the pressure of the crosshead downwards, the engine must be run over. By running a motor-driven compressor "under" or an engine "over," the wear is almost entirely on the lower shoe of the crosshead and, to maintain good alignment, this shoe alone will need adjustment.

A CHLORIDE SOLUTION

What is meant by a 2 per cent. chloride of calcium solution, and what quantity of chloride of brine would be obtained from a gallon of water when sufficient chloride of calcium is added to make a 21 per cent. solution?
A. STEVENS, Toronto.

Answer.—A 21 per cent. solution is obtained by dissolving 21 parts by weight of calcium chloride in 79 parts by weight of water. A cubic foot of water at 64 deg. F. weighs 62.3446 lbs., and a gallon of water at that temperature weighs $62.3446 \times 231 \div 1{,}728 = 8.334$ lbs.

The specific gravity of a 21 per cent. calcium chloride solution taken at the same temperature is 1.178, and therefore a gallon of the solution would weigh $8.334 \times 1.178 = 9.8174$ lbs. A 21 per cent. solution made from a gallon of water would contain $8.334 \times 21 \div 79 = 2.215$ lbs. of calcium chloride and 8.334 lbs. of water, making a total weight of 10.549 lbs., and therefore the volume would be $10.549 \div 9.8174 = 1.075$ gals.

KNOCK IN ENGINE

We recently purchased a second-hand slow-speed engine which since placed in use has a peculiar knock that appears to be due to looseness of the crank on the shaft. The shaft is steel 5 in. diameter and the crank is cast iron 4 in. thick. Would it be advisable to attempt electric welding without removing the shaft and crank from the premises?

Answer.—Ordinarily electric welding could not be satisfactorily performed unless at greater loss of time and expense than necessary to remove and rebore the crank, upset and refinish the end of the shaft and replace the crank with a good press fit. However, before deciding on the necessity for such a repair, it should be borne in mind that looseness of the crank would have grown worse so rapidly with continued use of the engine as to render the condition unmistakable in a very short time.

Frequently a creaking noise or peculiar knock existing in an engine for a long time is attributed to looseness of the crank, and later it is discovered that the noise proceeds from some quite remote part of the engine.

BOILER SCALE

Although the vibratory method of scale removal does very well for fire tube boilers, the writer frequently hears complaints about that method when applied to water tube boilers. Some manufacturers claim that it works as well in one kind of tube as in the other.

It is quite logical that when the tube of a fire tube boiler is rapidly tapped on the inside the metal of the tube will move or vibrate slightly, much like the ringing of a bell, and as a result the scale will drop off due both to inertia and to the slight bending effect in the metal scale is inelastic and brittle, while boiler tubes are elastic and tough. This difference in structure and characteristics makes it possible to remove scale very effectively by the vibratory process from tubes that can be set in vibration.

But when it comes to using the vibratory method in the tubes of a water tube boiler, it is not so easy. The same theory does not apply so readily and practice bears out the theory just as it should. In the water tube there is a constant variation in diameter of tube due to the thickness of scale itself within the tube. This makes it difficult and often impossible for the vibrating hammer to "make a good stroke." The strokes are therefore bound to be of variable length.

A high grade turbine cleaner for water tube boilers overcomes these objections. This kind of cleaner may not get ALL the scale out—a very thin scale may remain—but this can be remedied by running a vibrating cleaner through the tube after the turbine cleaner, should it be considered worth while and should it be found that the turbine cleaner is not thorough. It has been demonstrated mathematically and practically that thin scale causes more money loss in proportion to its thickness than does thick scale. This may sound paradoxical but it is the truth nevertheless, as borne out by recent experiments.

—W. F. SCHAPHORST, M. E.

The annual convention of the Northwest Electric Lighting and Power Association was held in Victoria, B. C., June 29 and 30. There were about seven hundred delegates present. The sessions were held in the Empress Hotel.

The employees of the Consumers Gas Co., Mutual St. branch, held their annual picnic on Saturday, June 14, at Wabasso Park. About 500 attended, and an attractive program was enjoyed.

The Dominion Tar & Chemical Co., Ltd., St. Boniface, Man., is in the market for complete equipment for boiler house and distillery, also for three storage tanks.

The Winnipeg Hydro Co., Winnipeg, Man., is in the market for superheaters for boiler and de-aerating open heater. The estimated cost is $20,000 and $10,000 respectively.

The Hydro Electric Co., North Bay, Ont., is in the market for three steam generators to replace those lost by fire at their sub-station at Gormonville.

To Avoid Clinkers While Firing

Practical Experiments at Wesley College, Winnipeg, Results in Cutting Fuel Cost

By C. F. RYE

FIRST it may be best to see what clinkers are; how they are formed, and what can be done to prevent them from forming.

Clinkers are the ash and unburned substances in the coal that have been heated above their melting point and work their way down to the grate where the fused mass is cooled and hardened.

Clinkers are formed in several ways; some of the most common being explained in the following: by sliding the slice-bar under the ash and fire, in so doing raising the ash up to the top of the fire exposing it to the intense heat The melted mass gradually settles back to the grates in the form of a soft putty, and as soon as it comes in contact with the cooler grates, and cold incoming air, it cools forming a hard clinker on the grates.

Heavy Charge of Coal

Another way in which clinkers are formed is by throwing a heavy charge of green or new coal on a bed of melting coal at a white-hot heat which cannot hold up under the load, and therefore, crushes down in a pancake style, stopping the draft at that place. In this compressed mass of coal and ash you have a splendid foundation for a clinker, from which one is sure to form.

A good illustration of compressing the coals and stopping the air is seen when a plumber uses oakum to stop a leaky joint in pipe connections. In its ordinary state it will not stop a leak, but when it is compressed it will be water tight. and likewise the ash and coal will be air tight.

From what we have gone over we have learned three important things:

First.—To keep ashes where they belong: not mixed up with the burning coals.

Second.—Do not throw a heavy charge of coal on the fire, instead of spreading each shovel of coal over at least four square feet of grate.

Third.—Do not burn rubbish or a fuel with a low melting ash.

Now after much experimenting we have come to the conclusion that the following is a splendid method to follow to avoid the formation of clinkers.

In starting the fire whether from kindling or bank, try to remove all clinkers, and start the fire near the front of the grates if you have not enough to spread over the whole of the grates. The first coal you throw on should be "nut and pea" size, which should be used until there is a good bed of coals then you are sure that you have a bed that will allow free passage of the draft, and yet a good solid bed that will not easily break down when new coal is thrown on. Now if you have slack coal, you can use it very sparingly, and in small quantities, well spread over a portion of the grates only. The best way we have found is as follows:

Imagine your grates in four sections lying in the same direction as the grates. If your fire box is four feet wide, then you have four sections each a foot wide.

If you use smoky or dirty coal you should fire only one section at a time of a very thin layer of coal. In this way the hot coals are not broken down with the weight of the new coal.

When you cannot get enough draft through the fire, reduce the thickness of the ash by shaking the grates, if the grates shake. If not, work the ashes through the grates by using the slice bar, but remember, do not raise the ashes in the fire.

In order to bank a fire without causing a clinker, the bank ought to be built up of thin layers of coal. In this way the weight will not crush down the hot coals, and each layer ought to be fired at intervals, so as to allow the smoke to burn off and allow the solid material or carbon in the coal to hold the fire without giving off smoke and soot to dirty your flues. Of course there are other ways to bank a fire, but this is the best method when new coal is used. In this way you will form a coked bank that will give much better results, and offer much less trouble in starting the fire, because you have a clean coked bed of coals that will break up in a form of coke, making a splendid bed on which to start a fire with little smoke, good draft and high economy and efficiency.

See Little Saving in Oil Fuel

Engineers of U. S. Bureau of Mines Oppose Changes Where Computed Economy Over Coal is Small

THE report of the Mechanical Engineering Division of the United States Bureau of Mines, opposing changes from a coal consuming to an oil burning basis in the heating plant of the Federal government institution on the ground of conservation of national resources will prove of interest to Canadian engineers as it leads to the conclusion that oil should not be used in stationary plants which show but small computed savings over using coal.

By a slight change in the furnace the Bureau of Mines engineers pointed the way to fuel economies at the plant in question. The tests showed variations in efficiency among the three shifts in the fireroom.

The report states that the plant could be changed to an oil burner at a cost of $33.500. to be amortized in five years. Assuming that oil could be contracted for at 3.5c. per gal. as contrasted with New River coal at $8.18 per ton. it is estimated the plant could save only $2,400 a year by changing to oil.

"Oil is a national resource which is limited in extent and must be conserved for military, naval, merchant marine and lubricating needs. To use it extensively in stationary plants brings nearer the time when the supply will be exhausted and the above needs for its best use will have to seek supplies in some other other form.

Oil Prices Now Low

"At present oil prices are low and therefore favorable to plants desiring to change from solid to liquid fuels, but no one can predict how long such conditions will exist. It is certainly true that a plant changing from coal to oil now will have to revert to coal again in the not too distant future. It seems advisable from a national resource standpoint that this plant continue on a coal-burning basis and bend their energies toward improvement in coal efficiency rather than seek a change to fuel oil now and later on change back."

The tests disclosed conditions which resulted in shortening the ignition arches 18 in. in consequence of which the over-all efficiency was increased 2 per cent.; the thermal efficiency of the boiler alone increased 4 per cent., while the heat absorbed by the superheater and by the economizer decreased 1 per cent. each; and the temperature of the gases leaving the boiler decreased 108 deg. while the rate of working the boilers decreased 20 per cent.

Previously, the steam pressure tended to fall continuously and to maintain it at the proper point the fuel bed had to be poked frequently. The poking of the fires broke up the caked fuel, which was then carried onward by the stoker.

Cut Ignition Arch

After the ignition arch was shortened, poking was resorted to only one-fourth as frequently, while the steam pressure was held five pounds higher with a maximum fluctuation of five pounds compared with a previous fluctuation of fifteen pounds. Also, it was not necessary after the change to blow the ash from the tubes. which had been done frequently previously in order to avoid complete obstruction, as the accumulation was negligible.

The tests indicated that if the plant is operated as well for the whole year as it was during the the tests. there will be an annual saving of approximately $10 000 in fuel cost.

EXCESS AIR COSTLY

(Continued from page 31) .. ..

parison with the volumes involved when measuring the output of blast-furnace gas or the air currents of an entire colliery. Thus, for example, in a large power station plant of, say, ten boilers of 60,000 lbs. evaporation per hour each, the total volume of air passing into the station would be about 250,000 cubic feet per minute. The advantage claimed for the "Pitot" tube or the "Venturi" disc principle is that the size of the recording mechanism is dependent of the volume to be measured.

In this way, for the first time we should get a boiler plant completely under scientific control, with a record of air and the fuel supplied and the water evaporated. It is tolerably certain that when this is done, many valuable facts will be discovered with regard to the air question, the relations between volume of air, composition of fuel, furnace temperature, complete analysis of the flue gases, and the net working efficiency of the plant, the result of which will be to increase the efficiency of steam generation. There is no reason also why the whole of the exit gases passing up the chimney should not be measured in the same way, if only as a test of the air leakage on the plant. One can only hope that further work of this character will be undertaken in Canada, especially since many engineers claim the United States is now ahead of us in boiler and power plant control.

Typical New Plant

At present little is definitely known about excess air, but it is generally believed that the latest type of mechanical forced draught and mechanical stoker for water-tube boilers will operate with 35 to 40 per cent. excess air, although presumably this figure is based largely on calculation, and not on actual determination. As typical of the latest practice in this respect, there is a new boiler plant projected in Great Britain with water-tube boilers of 8619 square feet heating surface. Each boiler is to evaporate 60,000 lbs. per hour at 210 lbs. pressure, and the steam is to be superheated to 677 deg. Fah. in a superheater of 3190 square feet heating surface.

The plant will include a special "tri-tube" cast iron economiser of 4620 sq. ft. heating surface—with entering feedwater at 180 deg. Fah.— and an air heater. The stokers are to be of the underfeed travelling grate design.

The guaranteed efficiency of this plant is 85 per cent. on the lower heating value of the coal, or deducting the power used for the mechanical draught—forced and induced draught fans—and mechanical stoker, about 88 to 88½ per cent., according to ordinary methods of calculation.

Apart from the fact that the whole question of boiler plant testing is in hopeless confusion and no proper test code exists, so that it is difficult to say what these figures actually mean, it is obvious that the above is a very high guarantee and involves the use of only about 37 per cent. excess air. This figure corresponds to 1,273,000 cubic feet of air at N. T. P. per hour, or 162.8 cu. ft. per pound of coal burnt, as the coal consumption is to be 7816 lbs. per hour. The coal, it may be stated, is of somewhat moderate quality, giving 10,800 B. T. U. on the lower heating value—whatever that means exactly—for the method of expressing the heating value of fuel is part of the general confusion.

The best results with regard to excess air are, of course, obtained with pulverised fuel, because of the intimate mixture obtained with the air and the fuel owing to the fine state of division of the latter.

Elaborate tests have been carried out in a plant which consists of eight water-tube boilers with superheaters and economisers working at 300 lb. pressure and fired by pulverised fuel, supplying 40,000 kilowatts. The figures of this boiler plant represent one of the most remarkable performances for steam generation in the world, averaging 85 to 86 per cent. efficiency, and the air figures—which were determined only with great time and trouble— are as follows for five typical tests at different loads on the boiler:—

Tests on One Boiler, Normal Duty 85/90,000 lb. per Hour.

Duty of boiler, evaporation in pounds per hour, average	53,390	83,953	81,121	57,572	92,202
Air—					
(a) Temperature entering furnace, deg. Fah.	86	89	91	104	93
(b) Pressure of air at pulverised fuel feeders, inchese W.G.	11.0	12.2	13.6	12.2	13.6
(c) Excess air in flue gases, per cent.	13.3	21.9	21.2	10.7	25.2
Flue gas—					
(a) CO2 in fourth pass, per cent.	15.8	14.6	14.7	16.0	14.1
(b) O2 in fourth pass, per cent.	3.3	4.6	4.6	3.3	5.2
(c) CO in fourth pass, per cent.	0.05	0.00	0.03	0.00	0.09
(d) Pounds dry gas pound coal, per cent.	11.04	11.63	11.37	10.06	11.56
(e) Temperature leaving boiler, deg. Fah.	434	475	482	430	496
(f) Temperature entering economiser, deg. Fah.	338	400	424	400	431
(g) Temperature leaving economiser, deg. Fah.	168	196	205	204	251
Draught—					
(a) At furnace, inches W.G.	0.017	0.19	0.16	0.045	0.206
(b) At fourth pass, inches W. G.	0.314	1.11	1.185	0.39	1.40
(c) Entering economiser, inches W.G.	0.424	1.23	1.28	0.40	1.66
(d) Leaving economiser, inches W.G.	0.525	1.67	1.72	0.51	2.38
Pounds water evaporated per pound of coal	8.92	8.62	8.49	8.66	8.12

The figures, therefore, for excess air vary from 10.7 to 25.5 per cent. excess over the theoretical, rising as the plant is forced. a very fair average for pulverised fuel being 20 per cent. excess, corresponding to 16 to 17 per cent. CO_2 at the actual point of combustion, although here again the methods used are not very clear.

TRANSFORMER TESTS

(Continued from page 40)

conditions, should be sufficient for the purpose. It is decidedly an advantage to carry out such megger tests. If the windings on either side have an earthed neutral, the earth should, of course, be removed before testing. If the phases on each side are connected (either in star or delta) one megger test only is necessary for each side, though if a fault be found it will be necessary to disconnect the phases to locate it.

Inspection of the different parts is, however, much more important, and for this purpose a transformer should, on the average, be lifted from its tank and examined thoroughly every six months.

It is not very likely that dust or any other foreign matter will have entered the tanks of transformers, if they are the modern products of a reputable firm, and no particular attention need be paid to this point.

REFRIGERATION ECONOMIES

(Continued from page 26)

brine, causing trouble with pump valves and pipes. Brine should be strained. A small strainer on the suction side of the pump will in a short time pay for itself in saving time and the annoyance caused by plugged pipes. The strainer should be kept clean and free from sludge, or the friction loss through it will be excessive.

A fine sediment will invariably collect on the inside of all brine piping, decreasing the velocity of the brine and interfering with the transfer of heat through the walls of the coils. Cleaning at regular intervals may be done readily by using high pressure steam.

Brine should not be wasted. For temperatures around zero 20 per cent. by weight of calcium chloride is required, costing $45 a ton, hence it can readily be seen that any leaks or waste by spilling, will, if continued over a period of time, result in considerable loss.

Save Water

Where city water is used for cooling purposes, the engineer can save money by care in the amount used in the condenser. When large quantities of water are used for boiler feed or other purposes in the plant the water may first be passed through the condenser. The danger then lies in using excess cooling water. Excess water cuts down the suction pressure, a smaller amount of gas then enters the cylinder for each stroke, resulting in a decrease in capacity unless the compressor can be speeded up. Sufficient water, however, must be passed around the condenser to liquefy all the gas.

In general it may be stated that insufficient cooling water results in high pressures on the suction side, an excess in low pressures. and, in consequence, decreased capacity.

The engineer in one plant saved three thousand dollars in a year by cutting down the amount of water passing through the condenser, at the same time increasing the size capacity of the plant.

CLASSIFIED ADVERTISEMENTS

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads set in border, are at the card rates.

Every Engineer, Mechanic and Electrical Worker will welcome this new master set. It will answer your problems.

It will help you with your daily work.—A sure source of advancement and higher pay. Complete up-to-date information that is thoroughly and easily explained on every branch of modern engineering and electrical practice.

AUDEL'S ENGINEERS & MECHANICS GUIDES

4750 PAGES — $1 A MONTH
8754 ILLUSTRATIONS — $12 COMPLETE

These Guides tell you all about—

Theory, Practice and Operation of ALL Steam Engines; UNIFLOW and POPPET VALVE ENGINES, and LOCOMOBILES. Locomotive-Marine Engines; Turbines; Rotary Engines --the Indicator -- Lubrication -- PRACTICAL MANAGEMENT. GAS, GAS ENGINES--*Aeroplanes and Aviation*--HOW TO SELECT AN ENGINE, STEAM ENGINE rules and formulas. Steam Boilers; Heat-Combustion; Fuel and Flue Gas Analysis-C02 Recorders-Construction of all types of Boilers,--Mechanica Stockers--Oil Burners--Setting--Chimneys--Mechanical Draught --HOW TO SELECT A BOILER--BOILER DESIGN based on A.S.M.E. BOILER CODE--OPERATION FIRING. Pipes, Fittings--Heating and Ventilation--Refrigeration--Cooling Towers --Condensers--Distilling Apparatus--Elevators--Cranes--Ropes and Cables--Splicing--*Practical Electrical Engineering* as an aid for engineers and electricians in obtaining a license--ready reference index, covering entire field of Modern Electricity.

SHIPPED TO YOU FREE

Not a cent to pay until you see the books. No obligation to pay unless you are satisfied. Send coupon now--today and get this new master set for engineers. Pay only $1 a month.

SEND NO MONEY

POSITIONS WANTED

FACTORY SUPERINTENDENT OR CHIEF Engineer is open for engagement. Have had wide experience in operating power plants and handling help in Canada. Apply Box 107, Power House.

REFRIGERATING AND MECHANICAL ENgineer with 10 years' operating record, also with experience in heating and lighting work, desires employment in Toronto. Apply Box 108, Power House.

POSITIONS VACANT

STATIONARY STEAM ENGINEER WANTED—familiar with water tube boilers and Turbo Blowers and Generators. Must be an all round competent man, capable of taking charge of plant of about 2,400 B.H.P. Must have first class certificate. State in first letter salary wanted, age, experience, and when you can report. Apply P. O. Box 720, Port Colborne, Ont.

WANTED — SALES ENGINEER—EXperienced in steam specialty lines. University graduated preferred. Write stating experience and salary. Apply Box 109, Power House.

FOR SALE

BURNHAM STEAM PRESSURE PUMP, 10 IN. x 1⅛-inch. x 12 in., nearly new, with Fisher governor attached. W. Ahearn, 538 McLaren St,. Ottawa. When answering this advertisement please mention this paper. P.F.H.

INDUCTION MOTOR — 220 VOLTS — 1800 r.p.m. 15 h.p.; single phase; can be bought cheap; write for particulars. Box 104, Power House.

I. H.C. 12 H.P. GAS ENGINE FOR SALE—ALL in good running shape, with 33-inch clutch pulley; will be sold reasonable on easy terms. Apply W. Harrison & Son, R. R. No. 5, Guelph. When answering this advertisement, please mention this paper. P.F.H.

TAYLOR SAFE FOR SALE

Inside dimensions 15" deep, 2 ft. 6" wide, 3 ft. 11½" high. We will accept $225.00 for this safe—a bargain for someone. Apply Box 110, Power House.

Nature's Water Softener
Copyright 1920—The Refinite Co.

For Boiler Feed Water

Refinite makes scale impossible. It takes out the scale-forming lime and magnesia before the water enters the boilers. You save not only fuel, but the trouble, time and expense of washing boilers and replacing tubes.

A coating of scale even 1-50 in. thickness wastes 100 lbs. from every ton of coal fired.

Write for Information and Catalogue.

Refinite Company of Canada, Limited
305 Continental Life Building, Toronto

TRIPLEX DRAFT GAUGE

Gives you accurate knowledge of furnace conditions at a glance. It indicates pressure in wind box, draft in furnace above the fire and draft in last pass.

It is designed and built for convenience of installation, maximum visibility and permanent accuracy. Each instrument must pass the Foxboro quality test.

Write for Bulletin CF-131.

Having Any Furnace Trouble

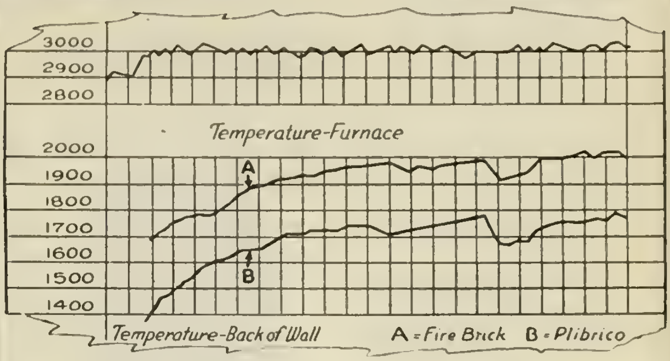
There's bound to be trouble in any furnace or fire-box soon after the edges of the brick start to disintegrate—it's the weakest spot. The only remedy is to eliminate all edges and built a one-piece lining with

STERNSON
No. 40 Monolith

A ceramic mixture of plastic and calcined refractories which can be molded into a jointless, gas-tight furnace or fire-box lining by inexperienced men. It is a positive protection up to 3,000 deg. F. as, when vitrified, it forms one great fire brick. The saving in price alone, compared with brick and mortar, is worth considering.

"Let a Technical Firm Do a Technical Job."

G. F. STERNE & SONS, LIMITED
Chemical Manufacturers,
Consulting Chemical Engineers.
BRANTFORD : : CANADA



Proof that Plibrico reduces heat radiation—

PLIBRICO far outlasts fire brick. Thousands of furnaces lined with Plibrico are proving this. Now here is proof that Plibrico keeps the heat in the furnace far better than fire brick.

Some time ago half of the back wall of a furnace was lined with Plibrico and the other half with laid-up fire brick. Then a test run was made, the temperature ranging from 2,900 to 3,025 deg. F. as shown by the chart above.

The chart tells the story of how Plibrico kept the heat in the furnace. The temperature of the outside of the Plibrico-lined wall (line B on chart) ranged from 1,400 to 1,770 deg. F.—the temperature outside of the fire-brick-lined wall (line A on chart) from 1,660 to 2,015 deg. F.

Don't you want the 50 page catalog "Modern Furnace Building" that shows how Plibrico cuts fuel costs and furnace maintenance costs? Your copy is waiting.

DISTRIBUTORS: Beveridge Supply Co., Ltd., Montreal; Shell Bar Boico Supply Co., Ltd., Toronto; Evans, Coleman and Evans, Vancouver, B. C.; Winnipeg Supply and Fuel Co., Winnipeg; Gorman's Ltd., Calgary, Alta.

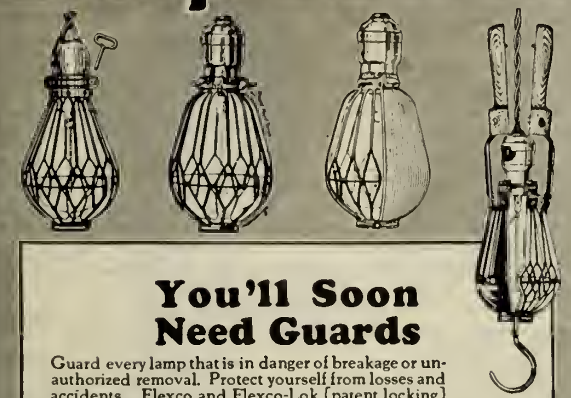
Lamp Guards



You'll Soon Need Guards

Guard every lamp that is in danger of breakage or unauthorized removal. Protect yourself from losses and accidents. Flexco and Flexco-Lok (patent locking) guards cost less than new lamps. Last for years.

Expanded metal reenforced construction. Attractive in appearance. Very rigid and strong. Made with key locking or plain round head screws. A style for every lamp.

Free sample 50 watt guard and complete information sent on letterhead request, mentioning socket size.

FLEXIBLE STEEL LACING COMPANY
469 Lexington St., Chicago, Ill.

"Maple Leaf"
Brand

Stitched Cotton Duck Belting *and* Dressing

It is water-proof and economical; also more efficient than other belting. The standard of quality, "Maple Leaf" Brand, is always maintained. That is why the demand for this belting is steadily increasing. "Maple Leaf" Brand Belting and Dressing make a good combination—use both.

Write for prices and further information.

Save Fuel

Fuel is scarce. Don't waste it. With the slightest variation in pressure the damper is automatically regulated in either direction by the

CURTIS

Improved Damper Regulator

It is a simple, durable and effective device. Positive and automatic in operation.

Write for our 1922 catalog showing the Curtis line of Engineering Supplies.

JULIAN D'ESTE COMPANY
26 Canal Street Boston, 14, Mass

A COMPLETE SERVICE IN
"John Crane"
FLEXIBLE METALLIC PACKING
"MADE IN CANADA"

Style 100. Babbitt foil, spirally wound and impregnated with purest graphite.

Steam and Air Rods

Every new steam pump or air compressor or centrifugal pump should be packed with Style 100 immediately upon placing it in service, if you desire to keep these rods in perfect condition. Friction will be greatly reduced and long, uninterrupted service will be the result.

Style 100 is a splendid packing for oil rods. It does not become saturated or deteriorate.

Use Style 100 on hand valves, header valves and Corliss valve stems.

Specify "JOHN CRANE" Packing on new equipment. Our book "METALLIC PACKING" (88 pages, illustrated) is free to all engineers.

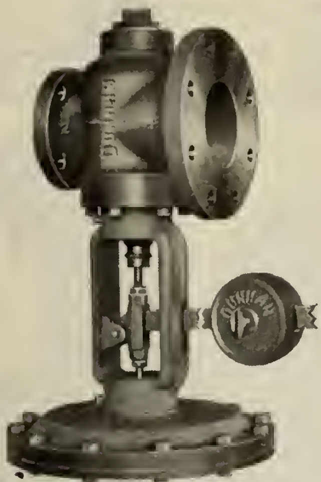
Dunham Reducing Pressure Valves Insure Constant Pressure Control



Dunham Reducing Pressure Valve, TYPE 310.
This valve has expanded outlet, facilitating quick reduction from high initial pressure to as low as atmospheric pressure. Also other types.

Dunham Reducing Pressure Valves reduce the pressure of steam, air, water or oil to any desired low pressure and hold it at that point, even if there is considerable variation on the high pressure side of the valve. They reduce in one step without chattering and are unusually capable in meeting sudden demands. They are applicable to a wide range of initial pressures and are made in straight as well as expanded outlet types.

Write for further information.

Anti-Clinker
SHELL-BAR GRATE BARS

Designed and built by men with practical experience, the Shell-Bar Anti-Clinker Grate Bars are built to

Get the last bit of heat out of the last bit of fuel

Write for full particulars

Maximum air space permits perfect combustion even of low-grade fuel. Nothing is burnt to waste—nothing is wasted in clinkers. Wherever they are used they are giving more heat with less fuel.

REDUCING VALVE PERFECTION

J.M.T.

A watchman who spends half his time sleeping is a poor asset to any plant. You wouldn't hire him for five minutes. Can you afford to be less particular of your Pressure Reducing Valves?

The importance of using valves which maintain correct reduced pressure at low maintenance costs cannot be over-estimated.

Morrison Valves are furnished for pressures from 5 to 300 lbs. They are the result of over 50 years' engineering experience.

Morrison Products include Valves for every service, Gauges, Injectors, Ejectors, Whistles, Bells, Steam Traps, etc.

"Belting trouble ends where D.K. McLaren's Belting begins"

YOUR GUARANTEE OF

GENUINE OAK

LONGER BELTING SERVICE

There are good reasons behind our claim that D. K. McLaren's belting reduces your transmission costs. In the first place only the toughest parts of hides, selected by experts, are used. These **Backs** are subjected to the **genuine British Oak Tanning,** a process that not only adds to their toughness but imparts a wonderful flexibility to the leather. It is this combination of toughness and pliability that gives to D. K. McLaren's Belting that gripping quality that prevents slippage and other troubles.

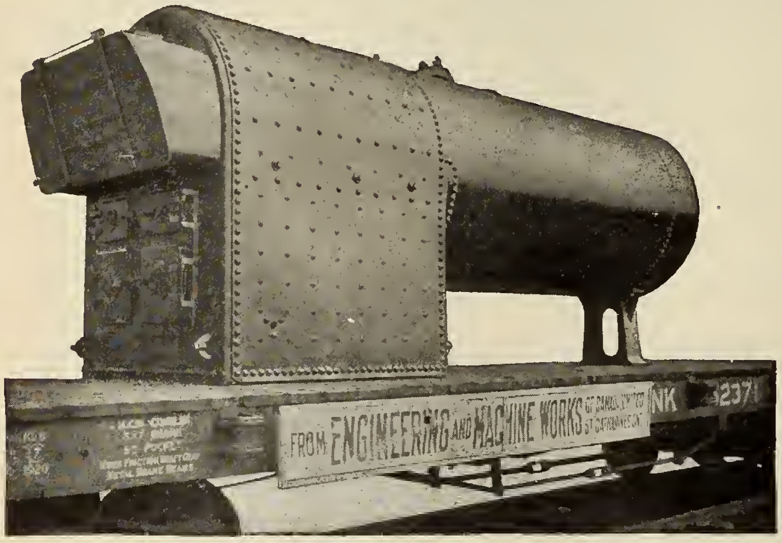
Boilers for Power or Heat



FROM ENGINEERING AND MACHINE WORKS OF CANADA LIMITED ST. CATHARINES ONT.
NK 32371

E. & M. W. Heating Boiler—Smoke Consuming Device can be added if desired.

Remember, a good Boiler is a real money saver.

Remember the old adage "any fool can make money but it takes a wise man to keep it."

Many a business firm to-day is losing a tidy little annual dividend because they cling to old-fashioned, leaky, coal-devouring Boilers, always "out for repairs."

We can equip you with a thoroughly high grade modern Boiler, for any duty, at a price so moderate that it will surprise you.

Users Testify to the Saving Power of Files Stokers

ONE user of Files Stokers says a single installation (3,600 H.P.) saved enough coal to pay for the stoker investment in five months.

The average rating for this period was 223%.

Another user has written to say "While we have not made an actual test we would judge the saving in coal to be 10% to 15% as our load increased 25%. We are now able to obtain required steam without difficulty, which we could not do with down-draft furnaces."

Quoting from the letter of a third user the fuel-saving merits of Files Stokers is attested as follows: "Our Files Hand Stokers have now been installed about two years, during which time they have paid for themselves twice over if we consider the saving in fuel."

Files Stokers Achieve Results because:

1. **They give correct distribution and proper proportion of air according to load carried.**
2. **The fuel bed is at all times kept clean and uniform.**

You will be interested in the details of design of the Files Stoker. Write for complete information.

BRANTFORD, ONTARIO, CANADA

The Polished Rod

The much desired "glass-like" polish on piston rods can only be maintained by the use of a packing that retains its elasticity and lubricant—not for a few hours after repacking, but during long service of changing pressures and temperatures. Rings of Garlock High Pressure Packing combined with our Diagonal Ring Packing makes a combination (Style No. 446) particularly adapted for service against medium or high pressure steam.

This combination will retain the polish and

COMPANY
OF CANADA
LTD.
MURPHY

ANY user of "Jones Standard" Stokers can, by adding the side dump attachments, convert his hand cleaned stokers into self-cleaning side dump stokers.

As shown in the illustration above, the change is a simple one. In place of the hand cleaned dead plates (left) sloping combustion grates and hand operated dump plates (right) are used. All of the features which have won fame for the "Standard" Stoker—simplicity, rugged construction, low maintenance, high efficiency and great capacity, to mention only a few—are retained.

The cost of the change is very low. No expensive ash pit construction is needed; an excavation of only a few inches is necessary.

Here is an opportunity for every "Jones Standard" Stoker user to get an ultra-modern side cleaning stoker for practically nothing. Don't pass it up. Send the coupon below to the Under-Feed Stoker Co. of Canada, Limited, 146 King Street, Toronto, for the cost of converting your hand cleaned stokers into self cleaning ones.

Plibrico puts an end to falling bricks

When furnaces are lined with fire brick, it is not long before the flame attacks the joints, causing the bricks to crack and spall. Soon they crumble and fall out, and the entire lining goes bad and allows heat to escape — just like the lining in the photo opposite.

Plibrico Furnace Lining eliminates this. Plibrico is pounded into place while plastic, and forms a **jointless** lining—a lining that lasts two to four times longer than fire brick, that resists heat to 3,100 deg. F.. and that cuts down heat radiation.

PLIBRICO
FURNACE LINING
JOINTLESS FIRE BRICK CO.

A typical plant of medium size showing Nonpareil Cork Covering on the brine and ammonia lines. S. E. Lux, Jr., Mercantile Company, Topeka, Kansas

Have You Short Lines like These?

SHORT runs of brine and ammonia lines need Nonpareil Cork Covering just as much as long ones. In proportion to size, the saving is just as great on 20 feet of 2-inch line as on 200 feet of 8-inch. It pays for itself in less than a year.

Take an installation like that shown above, which is typical of thousands of small plants. It is surprising how quickly you can put on 40 or 50 feet of Nonpareil Covering with 10 or 12 fitting covers. It all comes in sections ready to apply — no wrapping or trowelling or waterproofing.

And best of all, it is there for good. Nonpareil Cork Covering, applied properly, is permanent insulation. No drip, no frost, no repairs. Keep the wires tight and paint it once a year and Nonpareil Cork Covering will last as long as the pipes.

Write for the new booklet, "Permanent Covering for Refrigerated Lines and Tanks"—Sent free on request

Armstrong Cork & Insulation Co., Ltd.

902 McGill Bldg., Montreal, Que. 11 Brant St., Toronto, Ont. Can.

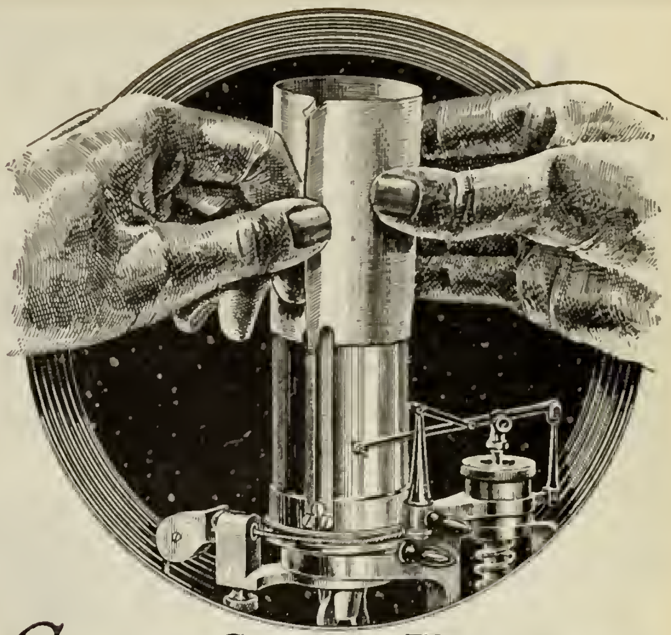
Nonpareil Cork Covering

For Brine and Ammonia Lines



Changing Cards at High Speed Without Unhooking Cord

While your engine is running at top speed you can change cards on an American Thompson Improved Indicator in less time than it takes to talk about it.

With our patented design of Detent Motion two or more cards can be taken in the time ordinarily required for one. You don't have to unhook cord, and the cord will remain at same tension.

AMERICAN
THOMPSON
IMPROVED INDICATOR

is the only make with this Improved Detent Motion. And without this device it is a slow, disagreeable and often difficult task to take off one card and put on another.

The American is also the most accurate Indicator. Because of its limited pencil motion, it is impossible to make the errors in vertical lines which usually exist in the diagrams taken with other Indicators.

This, and other features of the American are clearly explained in our booklet T-33, sent free on request.

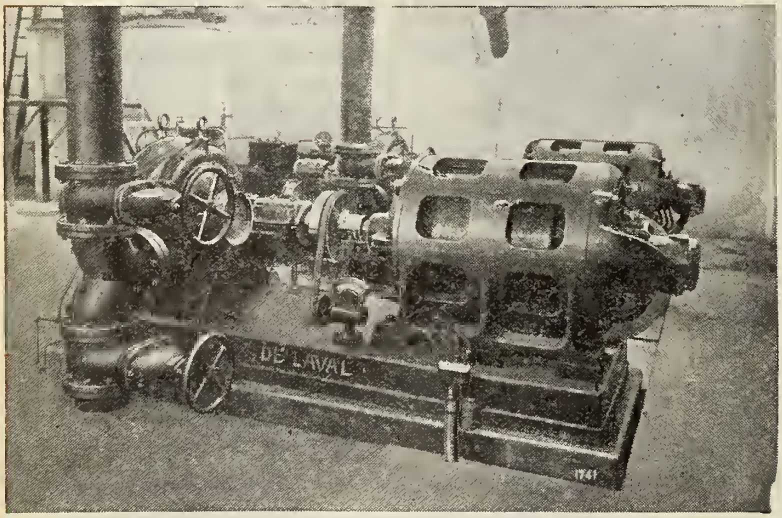
Pressure Easily Regulated



THE two De Laval two-stage 8-in. centrifugal pumps, designed for 1440 g.p.m. each against a maximum head of 325 ft., shown in the photograph, are installed in the water works pumping plant of Orillia, Ont. They are driven by variable speed motors, by means of which the pressure upon the system can easily be varied. Upon each base plate is mounted a tachometer driven by belt from the motor coupling, also suction and pressure gages, so that the operator can at all times know the speed and the pressure developed, from which it is possible to determine approximately the amount of water being delivered.

Describe your pumping requirements and our engineers will be glad to make suggestions. Ask for special publication B-100.

THE STANDARDS OF PRACTICE

to which

BUSINESS NEWSPAPERS ASSOCIATION
OF CANADA

members are required to conform

B.N.A. Standards of Practice

The members of this Association shall dedicate their best efforts to the cause of business and public service, and to this end shall pledge themselves:

(a) To consider first the interests of the subscriber.
(b) To work for truth and honesty in all departments.
(c) To eliminate, in so far as possible, their personal opinions from their news columns, but be leaders in thought in their editorial columns and make their criticisms constructive.
(d) To refuse to publish puffs, free reading notices, or paid write-ups, to keep their reading columns independent of advertising considerations and to measure all news by the standard "Is it real news?"
(e) To decline any advertisement which has a tendency to mislead, or which does not conform to business integrity.
(f) To solicit subscriptions and advertising upon the merits of the publication.
(g) To supply advertisers with full information regarding character and extent of circulation, including detailed circulation statements, subject to proper authentic verification.
(h) To co-operate with all organizations and individuals engaged in creative advertising work.
(i) To avoid unfair competition.
(j) To determine what is the highest and largest function in the field which they serve and then to strive, in every legitimate way, to promote that function.

It will be conceded that the working principles of the B.N.A. are unsurpassed in the field of advertising and publishing. They are not just a set of "dreamy hopes." Member publications must be dedicated to the true service of industry, must have high editorial standards, and their circulation methods and claims must be audited by the Audit Bureau of Circulations and be like Caesar's wife "above reproach."

Only publications that are willing and able to live up to these high standards are members of the Association.

Adherence to these standards makes B.N.A. publications leaders in their respective fields.

B.N.A. membership to a business paper is what the "Sterling" mark is to silver.

JENKINS

Extra Heavy Iron Body Globe and Angle Valves

Maximum strength and rigidity are rigorously preserved throughout in the design and construction of Jenkins Extra Heavy Iron Body Valves. This reserve strength amply meets the strains and stresses due to expansion and contraction of piping or other causes.

These valves are suitable and guaranteed for 250 pounds working steam pressure, or 400 pounds working water pressure—the margin of safety is wide, for each valve before it leaves the factory is tested to 800 pounds hydraulic pressure.

The bodies of these valves are made of high-grade cast iron; the spindles are manganese bronze, having a tensile strength from 50,000 to 60,000 pounds per square inch. Regrinding discs and seat rings made of durable steam metal.

KERR

"Guaranteed" Satisfaction

FORTY years' experience has shown us that Satisfactory Valve Service can be attained only by conforming to the most modern and approved practice in both design and construction.

It is this policy, together with the exercise of the greatest care in every detail of the work and the severe tests to which all our goods are subjected, that is behind the KERR Guarantee of Satisfactory Service—a guarantee that backs every sale of KERR Goods.

Save the cost of a shut-down with a Yarway Pipe Clamp

A leaky pipe is a needless expense. Stop the loss in a few minutes' time with a Yarway Pipe Clamp; making either a permanent or temporary repair.

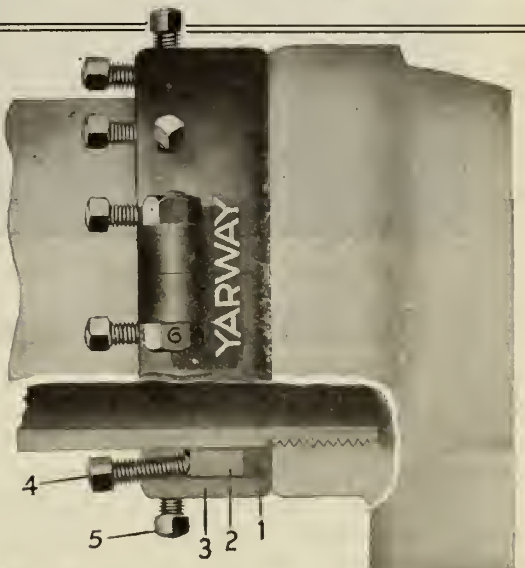
Yarway Holtite Pipe Clamps are for straight pipes. And Yarway Pipe-Joint Clamps are for leaky joints. They are both made in all the usual pipe sizes from ½" to 24" and are stocked by dealers in all principal cities for immediate shipment.

A satisfactory method for temporary or permanent pipe repairs.

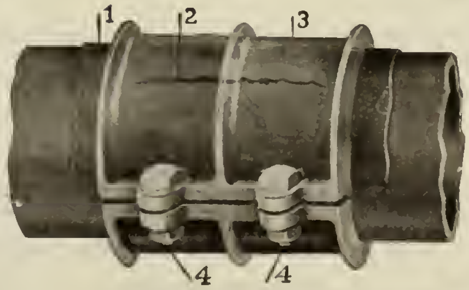
Comments of users are interestingly given, with prices, in Booklet C-805. Send for your copy to-day.

YARNALL-WARING COMPANY

Mermaid Lane and Ardleigh Sts., Philadelphia.
207 St. James St., Montreal.
400 Penobscott Bldg., Detroit.



Yarway Pipe-Joint Clamp. Stops Leaks at Threaded Joints.
1—Square packing ring, forced against leaky joint.
2—Inside ring, forced against packing 1 by screws 4.
3—Outside ring, bolted around pipe by bolts 6, secured by set-screws 5, prevents slipping when adjusting screws 4



Yarway Holtite Pipe Clamp Stops Holes and Splits in Straight Pipe.

Packing (1) is placed over split or hole (2) in pipe; metal clamp (3) is then fitted around pipe and over packing, and tightened by bolts (4)

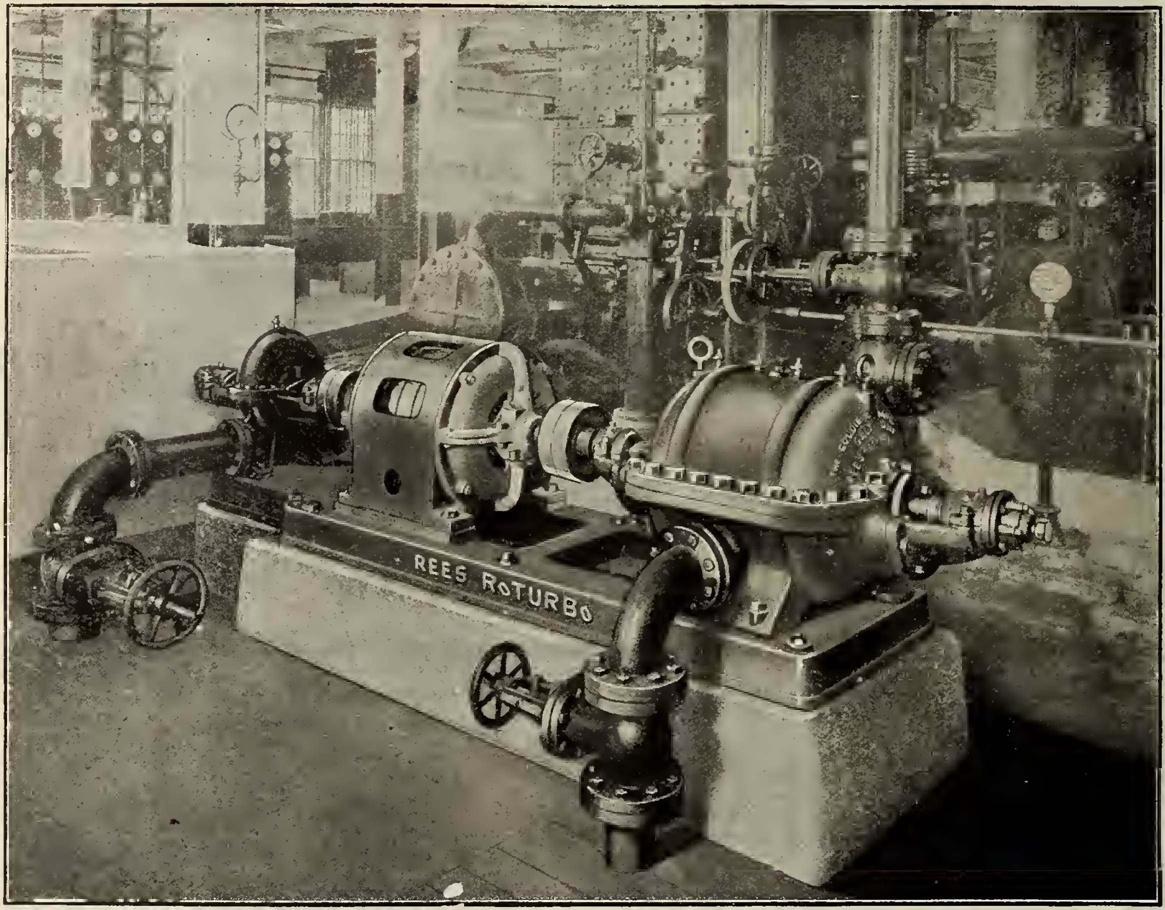
GOLDIE & McCULLOCH

REES RoTURBo PUMPS



Showing a Rees RoTURBo Two Pressure unit at the plant of the St. Lawrence Paper Co., Three Rivers, Que.

Patent Pressure Chamber Cannot Overload the Prime Mover

The Self-Regulating feature of the RoTURBo PUMP when subjected to variation in boiler pressure cause it to adjust itself to meet the new conditions without danger to the prime mover.

The fluid velocities are low, reducing friction losses to a minimum, and no wear is shown even from gritty waters. High permanent efficiency means that the REES RoTURBo is ideal for multi-stage operation—it is a pump in fact for any service.

REES RoTURBo Patent Pressure Chamber Pumps are to-day giving splendid service the world over in MINES, POWER STATIONS, MARINE SERVICE, WATERWORKS and ALL KINDS of INDUSTRIAL PLANTS.

Catalog mailed promptly upon request.

Perfect Power Efficiency

IF AN engineer went to a pump manufacturer to obtain a pump with a capacity of one quarter gallon to a gallon a minute, to handle warm salty fluid night and day, without a shutdown, working seventy strokes a minute and guaranteed to operate for seventy years without repairs or attention, would he get a price on such equipment?

If the manufacturer was alone in his office and timid he'd probably tell the engineer that as the job would require a lot of figuring he'd better come around next week, meanwhile edging his prospective customer toward the door before his insanity took violent form. On the other hand, if the manufacturer was made of sterner stuff he might say: "You fool, such a pump never existed or never will except in the brain of a lunatic such as yourself." Which would show how much he knew about it for every engineer carries just such a pump around with him and wouldn't sell it to anyone at any price.

No power plant as yet can boast as efficient a method of converting fuel into energy. It is doubtful if any plant will ever have as well designed a pumping system nor one as perfect for the disposal of waste.

Talk of modern combustion efficiency—the best that science can put into a boiler room is crude indeed compared with that of the human body.

An Analysis of Torque

POWER equipment of the heavier types is so readily rated in horse power that the term torque is seldom used and as a result the ideas of many engineers concerning it lose clarity, although in shafting and gearing problems a thorough grasp of its fundamental implications is of value.

For instance, 5 horse power at 250 r.p.m. can be transmitted by a torque of about 1,260 in.-lb., but the same power at 25 r.p.m. would require 12,600 in.-lb. and a much larger shaft. Indeed it is surprising what a dangerous torque may be produced by little power if the speed be brought very low through gearing or other means; 1 horse power delivered at 1 r.p.m. corresponds to about 63,100 in.-lb., which requires a substantial shaft and gearing.

These effects are generally veiled through the inefficiency of the gearing. If the power output of a motor driving the shafting of chain grate stokers, for example, be compared with the actual power utilized in moving the grates it will generally be found that about three quarters is wasted in speed reducing apparatus.

The torque on the driving axle of a stoker probably corresponds to but a fraction of a horse power, at the crawling speed at which such equipment operates; several times this power may be absorbed in the belts, worm gearing and other means adopted to reduce the speed of the driving motor.

An understanding of torque explains why a high speed electric motor is cheaper than a low speed design, apart from any advantages in production. A given size of motor frame will, within limits, produce a definite torque irrespective of speed. If the speed be halved, the torque remaining constant, only half the power can be produced, since power varies as torque times angular velocity; so that if a given power be required at a speed lower than the normal maximum, a larger frame must be employed, with a larger shaft and other disadvantages.

Torque measurement is best undertaken by some form of torsionmeter, which reads the elastic twisting in a given length of shaft. Previous calibration is necessary as well as means of measuring the speed of the shaft accurately.

The use of some such apparatus is the only convenient method whereby power, developed by turbines which do not drive generators, can be checked in the power house.

Economies of Efficiency

THE man who is interested in his work is always more valuable to an employer than the man who merely "holds" his job; what operating engineer in Canada can maintain his interest in running a plant if he has no idea of the results he is obtaining? He certainly cannot improve upon an unknown result.

The incentive to achieve economy in the operation of a power plant, by the installation of the most reliable equipment obtainable, cannot be calculated in dollars and cents alone, for evidence that efficiency is being attained is apparent in the enthusiasm shown by engineers and firemen who know their results, in striking contrast with the studied indifference of those who simply maintain the supply of steam demanded.

In the latter case the operating force quickly becomes mediocre in every way, waste abounds, and this state of affairs is by no means entirely the fault of the engineer in charge.

The "chief" in a properly equipped plant cannot do other than transmit some of his enthusiasm to those under him, and the result is beneficial in every way. Grievances and waste are noticeably less in boiler rooms where the engineer in charge is imbued with a keen desire to achieve better results. To maintain consistently a high state of efficiency the necessary interest can best be sustained by the provision of apparatus to lessen the labor and appeal to the intelligence of the firemen, to refuse to install such equipment on the grounds of economy is a very short-sighted policy.

Efficiency with economy is quite unattainable under present day operating conditions without accurate information on all the various operations involved in running the modern power plant.

Too Old? Not if He's a Hundred

WHEN an engineer writes a good letter to Power House—the kind every engineer likes to read—why is it that he frequently scribbles "Don't publish my name" at the bottom? It happens every week and it must be assumed that the writer has good reason for the request else he wouldn't be so particular.

The writer of a letter received this week, however, gives his reason for wanting his name kept secret and it's a mighty poor reason.

He says: "If my name is printed some of the members of the association will josh me about being too old to have any opinion worth while on modern power plant operation."

Too old? Not a bit of it—not if he's a hundred—his advice is but the more valuable. The only man who is proof against inspiration obtained in the school of experience is the dead one.

Buying the Right Coal for Power Plant Economy

By ROBERT JUNE, Assoc. Mem. A.S.M.E.*

The Adoption of the Right Fuel to the Right Equipment is a Problem, the Correct Solution of Which Offers Unusual Opportunity to Effect Operating Economies

THE proper selection of coal, the adoption of the right fuel to the right equipment, is a problem, the correct solution of which offers unusual opportunities to effect economies in the operation of the power plant. It is a problem which should ever be taken into consideration in the design of a plant.

The distinctions between the various ranks of coal are not clearly defined. The most satisfactory method for establishing the various classifications is by the use of both mechanical and physical criteria. On this basis the following ranks are arrived at:

The outstanding characteristic of anthracite is its low volatile content. Because of this it burns with very little flame, giving an intense fire free from smoke. Good anthracite is hard, compact, and lustrous, giving a vitreous fracture when broken. The chemical composition and heat value of anthracite is shown in Fig. 1.

Loss in Anthracite

An important source of financial loss in the use of anthracite lies in the fact that no matter how carefully handled, it is liable to break up into very tiny pieces, under the influence of the high temperature of the furnace, when freshly fired, with consequent, large losses of fuel through the grates to the ash pit. As anthracite requires at least 40 per cent. greater combustion space than does bituminous coal, it should never be purchased for use in furnaces not designed for it.

Semi-anthracite reaches the consumer generally under the name of "anthracite," a deception which should not be tolerated. As the name implies it is inferior to anthracite. It has less fixed carbon and somewhat more volatile. Its characteristics are likewise given in Fig. 1.

Super-bituminous fuel is commonly termed "Semi Bituminous"—an unfortunate appellation as it creates the inference that this coal is inferior to bituminous whereas it is markedly superior.

Another trade name for this fuel is "Smokeless" coal. The latter term is a consequence of the relatively high percentage of fixed carbon which renders the coal practically smokeless when properly burned. The heat value of this fuel is very high and as it requires less bunker and storage space per unit of heat than other coals it is in great demand for naval and steam-ship use, as well as for manufacturing plants located in crowded quarters where storage space is at a premium and smoke regulations are enforced.

This is the first in a new series of articles by Robert June, the well known authority on Power Plant Management. The articles are written from the point of view of the executive and deal with the dollars and cents end of power plant operation and maintenance. Succeeding articles will deal with such live topics as Efficient Combustion Practice, Safe and Efficient Boiler Operation, Stoker Operation and other problems of the stationary engineer.

Coal Quite Friable

Super-bituminous coal possesses one characteristic which the public has been prone to regard as a rather serious disadvantage; that is the coal is quite friable, readily breaking into small pieces not only during the process of mining, but also in transportation and handling. This apparent disadvantage is not necessarily existent as the coal can be burned with practically no loss through the grates to the ash pit, when fired with mechanical stokers and grates adapted to the fuel. Reference again is made to Fig. 1 for outstanding characteristics.

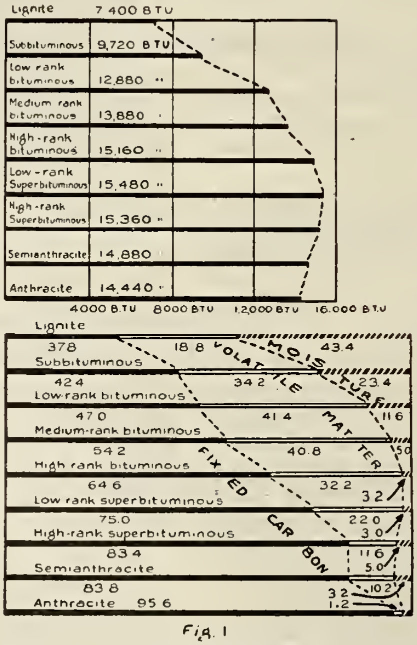

Fig. 1

Comparative heat value, and variations in fixed carbon, volatile and moisture of different coals, computations on ash free basis.

The term bituminous is applied to a wide variety of fuels. The classification "bituminous" is based in particular upon the relation of volatile matter in the coal to fixed carbon, but also and more specially to the factor which distinguishes bituminous coals from those of lower rank. This factor is that true bituminous coal is only slightly affected mechanically by weathering even though it be exposed for a long period of years. This is not true of coals of lower rank, which break up readily under the influence of weather.

Many attempts have been made to divide bituminous coals up into characteristic groups. This is not readily accomplished but the following classifications tell the power plant operator what he ought to know.

(a) Non-Coking, dry bituminous coals are the best for steaming purposes. They closely approach super-bituminous in character, being hard and dense but inclined to be friable, breaking easily in transportation and handling. They ignite readily, and burn freely with short, clean, bluish flame.

Fuse in Burning

(b) Bituminous coking coals as their name implies swell up, becoming pasty and fuse together in burning. They have a higher percentage of volatile and less fixed carbon than the free burning non-coking coals. Being rich in hydro-carbon these coals are particularly adapted to gas making. Certain varieties are commonly sold as "Gas Coal."

(c) Long-Flaming, bituminous coals are notable smoke producers. Some varieties coke, others do not so in using coal of this grade for steam purposes care should be taken to secure a supply at all times from the same source; otherwise uncertain combustion conditions will prevail and financial loss ensue. As a general proposition this coal is preferable for use under dryers, in cement kilns, and so forth, rather than for general steam making purposes.

The distinction between sub-bituminous and bituminous coals lies in the fact that sub-bituminous rapidly loses its moisture and consequently "slacks" to a marked extent when subjected to alternate wetting and drying. As the matters of both size and moisture content are important in buying and shipping coal, there are a number of points to be considered before voluntarily adopting sub-bituminous coal for use in the power plant. For one thing,

---

*Copyrighted, 1923, by Robert June.

unless slacking is to be permitted, it is almost necessary to ship sub-bituminous coal in box cars, thus materially increasing the cost of loading and unloading. Another point is that sub-bituminous coal is extremely liable to spontaneous combustion. On the other hand sub-bituminous is a very clean fuel and ignites with little difficulty.

Brown in Color

As used by the Geological Survey the term "Lignite" is restricted to those coals which are distinctly brown in color and either characteristically "woody" or "clay like" in their appearance. Because of their high moisture content which may run up to 30 or 40 per cent., these coals cannot be shipped far as no one wants to pay freight on so much water. Lignites are even more difficult than sub-bituminous coals to handle because of their rapid loss of moisture and marked tendency to slack and to spontaneous combustion. For economical steam generation lignite should be purchased near the power plant and practically used as rapidly as received.

Comparison of Ranks

Fig. 1 shows proximate analysis of B.t.u. value of the various ranks of coal. This diagram is best on the properties of actual samples of commercial fuels in each rank. Fairly regular increase in fixed carbon from lignite to anthracite will be noted. The rapid increase in the moisture in the lower ranks of coal is of interest as is also the fact that the greatest amount of volatile matter is found in the lower ranks of bituminous,

The diagram shows the B.t.u. value of the coals on an ash free basis. It will be seen that the best coal for steaming purposes is low rank super-bituminous.

Moisture in Coal

Not only is moisture a non-combustible but it absorbs heat because it must be vaporised and discharged at stack temperature. Where the moisture percentage is small this is not such a serious matter, as one per cent. of moisture amounts to only one-tenth of one per cent. of 13.000 B.t.u. coal if we assume somewhat high stack temperature of 700 degrees.

Another point with respect to moisture is important; the usual chemical analyses of coal do not show all of the moisture. The reason for this is that there is considerable amount of water which cannot be driven out of the coal even at 220 degrees F., but remains in chemical combination usually as a carbo-hydrate which can only be driven off with volatile.

In a typical West Virginia coal, 13% of the volatile has been found to be water. In a typical Illinois coal 25% of the volatile itself is non-combustible in the form of water. This means that in making comparative appraisals of coals from different fields or in purchasing coal under specification the moisture content of the volatile as well as the free moisture should be taken into consideration to secure accurate results.

Ash is a complex compound consisting of iron, lime, alumina, magnesia, silica, titanium and various alkalies.

An Inert Material

It is to be considered from two points. First, in buying coal with any appreciable percentage of ash in it you are paying not only the first cost but also freight and handling charges all through your plant for so much inert material. The second, is of utmost importance. It concerns us with the fusing temperature of the ash and the actual temperature to which the ash is subjected in the furnace. There are coals, the ash of which has such high fusing temperature that there are practically no fuel bed conditions which will produce troublesome clinker. Next we find a different type of ash with a lower fusing temperature. This ash will clinker but in doing so it forms a porous spongy mass which does not materially obstruct the flow of air nor prove difficult to remove. The really troublesome ash is that which has a low fusing temperature—say 2100 degrees F. This forms the worst sort of clinker, and the question of the use of coal which contains it should be given the most careful consideration by the power plant operator.

Influence of Size

Bituminous coals are graded and sized as follows:

(a) Run-of-mine — unscreened coal which has been picked over only for removal of larger pieces of foreign material.

(b) Lump—coal which will pass over a bar-screen with 1¼ inch openings.

(c) Nut—coal passing through bar-screen with 1¼ inch openings and over a screen with ¾ inch openings.

(d) Slack—coal which passes through a bar-screen with ¾ inch openings.

Anthracite coal is graded and sized as follows.

(a) Run-of-mine — unscreened coal from which larger pieces of foreign material only have been picked.

(b) Lump—classed as 6 inch, 3 inch, and 1¼ inch according as the coal passes through circular openings of the larger diameter and over openings of the smaller diameter.

(c) Nut—classed as follows:

Three inch—smaller than 3 inches and larger than 1¼ inch in diameter. One and quarter inch—smaller than 1¼ inch and larger than ¾ inch. Three quarter inch—smaller than ¾ inch diameter and larger than five-eighths inch.

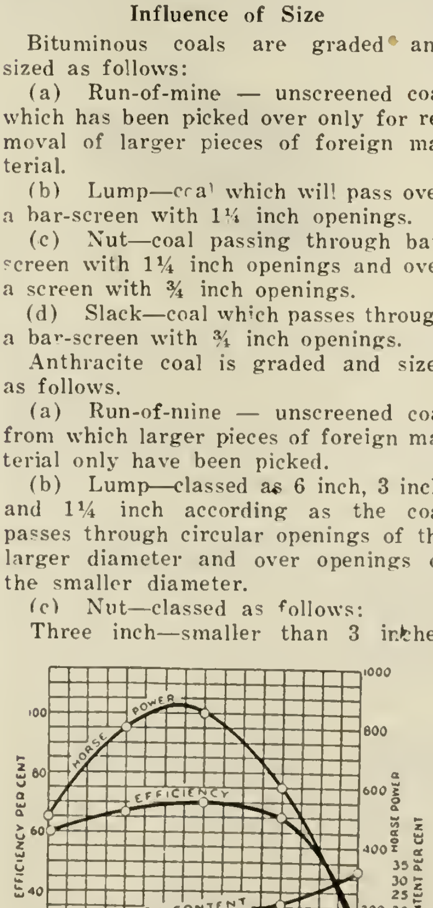

Fig 2

Influence of size of screenings on capacity and efficiency of a stoker fired 500 H P. boiler.

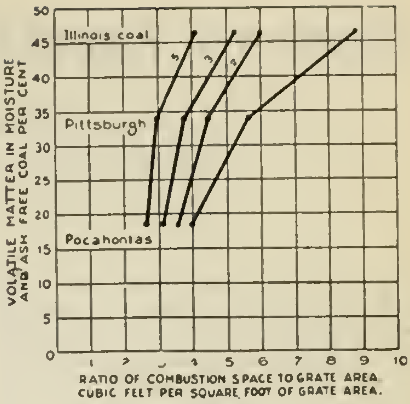

Fig. 3

(d) Screenings—everything which passes through a 1¼ inch screen.

The size of coal effects the draft of the furance and influences the capacity of the boiler. Thus, the presence of large quantities of fine coal and dust will materially check the flow of air through the fuel bed. When fine coal is used thin fires are necessary, and this usually results in a decrease in boiler efficiency due to the presence of holes in the fire.

The percentage of ash in fuel generally increases materially as the size of the coal decreases. The explanation is that dust and small pieces of foreign material from the roof or floor of the mine, having been separated from the larger coal naturally finds their way into the smaller coal. Fig. 2 illustrates the influence of the size of screenings on the capacity and efficiency of a 500 h.p. boiler fired by chain grate stokers.

The size of coal best suited to individual plant operating conditions should be determined by a series of tests. Once the most efficient size has been determined it will be found profitable to insist that all deliveries conform to this size.

Combustion Space

Different coals require different combustion spaces—the size of the combustion space required being determined by the quantity and quality of the volatile matter as indicated by the ratio of volatile carbon to available hydrogen, and also by the oxygen content of the coal on a moisture and ash free basis.

Fig. 3 furnishes an illustration of the point that the size of the required combustion space is dependent upon both the quantity and quality of the volatile matter and does not depend upon the percentage of volatile alone.

It is well worth while to have the combustion space in your furnaces checked up against the coal which you are now buying. In putting in new boilers be sure that the combustion space in the furnaces is designed for the coal which you can buy to best advantage.

It is important to know the B.t.u. con-

How to Keep Oil Engine Bearings in Alignment

Radical Difference in Combustion of Cylinders and Lack of Uniformity in Grade of Babbitt Among Problems Confronting Power Plant Engineers in Canada

ONE of the first things the operator of an oil engine must understand is that the crankshaft bearings must be kept in line. It formerly was the custom to ascribe the breaking of crankshaft to crystallization or improper heat treatment of the metal during the forging of the shaft. Other explanations have been offered, such as hydrogen embrittlement, meaning that during the heating of the billet hydrogen was encased in the steel, and upon meeting with oxygen left the metal and weakened the structure.

Of late, investigation of many fractured shafts has proved that in all these cases of damaged oil-engine crankshafts the cause of the fracture could be traced to misalignment of the main journal bearings. It is not claimed that no shaft has been broken by other causes; but of those examined, all showed at the fracture signs of the edges of the fracture having rubbed together by reason of the bending of the shaft, and, upon checking the bearings in all cases one or more bearings were found to be low.

It has been proved by exhaustive experiments that a shaft that is forced to bend at each revolution, as in the case of uneven alignment, will run a definite number of revolutions, after which it will break. The total number of times before fracture depends upon the metal, the diameter, and the amount of flexure. If these factors are known, the length of shaft life may be predicted with fair accuracy.

Discrepancy Unavoidable

No set of shaft bearings is ever absolutely in alignment; even when leaving the test floor the discrepancy will be around 0.01 in. With this amount of flexure the shortening of life is negligible; but when the discrepancy amounts to 1.32 in., the shaft life is reduced as much as 90 to 95 per cent. No shaft should be allowed to run for any length of time with a low bearing.

The question naturally arises, How may the engineer keep the bearings in alignment, and how may he learn whether one or more are low? A moment's consideration will cause one to concede that it is impossible to expect babbit bearing to wear at the same rate, even though the pressure be the same. In the actual engine it is quite customary to find the combustion in the several cylinders to differ quite radically. Often the cylinder pressures vary as much as 25 per cent. This means that 25 per cent. greater pressure is exerted on the two main bearings adjacent to this cylinder than upon the remaining ones. With the same babbitt lines these two bearings will wear faster. This means that soon the shaft has a perceptible kink in it, and at each revolution is flexed back and forth. Finally the shaft gives way.

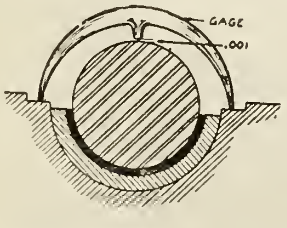

FIG. 1.

Second Cause of Wear

A second cause of rapid bearing wear is a difference in the grade of babbitt, or in the amount of peening done on it. The softer babbitt wears faster, throwing the shaft out of line.

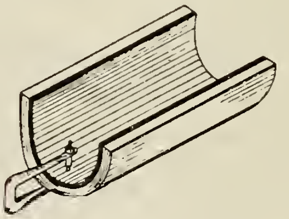

FIG. 2.

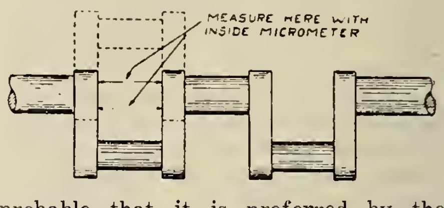
The engineer is then confronted with the problem of how to avoid this trouble. He cannot alter the character of the babbitt put into the bearing shell, but he can control the cylinder pressures. For this reason he should purchase an indicator, and occasionally take indicator cards from each cylinder. If the compression pressure in one of the cylinders is higher or lower than the others, it should be brought to its correct value by placing additional shims, or removing some of the shims from between the big end of the connecting-rod and the crankpin bearing. If the injection period is longer or shorter in one of the cylinders, by shifting the fuel-cam nose the correct injection period can be obtained.

These are the ways in which the bearing wear may be kept as near uniform as possible. But the engineer is confronted with the question of how to check the shaft alignment to find if things are in proper condition. Two methods may be followed, or a combination of both.

The first method to be outlined is the easier one, and for this reason it is probable that it is preferred by the majority of those engineers who attempt to keep shafts in alignment.



A gauge, as shown in Fig. 1, is made up out of sheet steel of, say, ⅛ in. thickness. This gauge is so made that when its two legs rest upon this bearing housing, the anvil just clears the shaft by 0.001 in. Gauges should be made for each bearing and numbered so that no mistake can be made. If the engine is a high-grade one and has had the housing planed and bored at one setting, the housings are all in alignment. One gauge only is needed under such circumstances.

Now, if a bearing wears, the shaft will, of course, bend until it rests upon the babbitt. This, then, causes the shaft surface to be lower than before the wear occurred. If the gauge is now placed on the bearing, the clearance between the shaft and gauge anvil will be more than the original 0.001 in.

An Accurate Method

A second method is more accurate, and is largely used by oil-engine builders.

The majority of engines have the housing bored for the bearing shells at the same time. The only difference in the misalignment of these housings is the slight inaccuracy of the boring mill. This difference should not be over 0.001 in.

The babbitt metal is cast into a steel or cast-iron bearing shell. These shells rest in the housings and are within 0.001 in. of being true. The difference in bearing heights will not exceed 0.002 in. If this thickness of the bearing shell was known, then any later wear could be detected by a decrease in the thickness of the bearing shell. A large gap micrometer may be secured from any gauge maker. This is similar to that shown in Fig. 2. By measuring the bearing shells when the engine is erected, any wear and shaft misalignment can be detected by rolling the shell out and remeasuring the thickness. This should be done at a point about 2 in. from each end of the babbitt liner about every six months.

Naturally the question arises: How

(Turn to page 44)

Solving Under Capacity of Absorption Systems

By C. O. FEHL*

A Description of the Modern Refrigerating Machine of This Type, Its Operation and the Causes to Which Under Capacity Can Usually be Attributed

THE modern absorption refrigerating machine consists of the following parts: a generator, an analyzer, a dehydrator, a condenser, a receiver, a weak aqua ammonia cooler, an exchanger, an absorber, a strong aqua ammonia tank, an ammonia pump and the evaporating system. The latter can consist of any apparatus with which evaporating ammonia can take up heat.

The main difference between a compression and an absorption machine is this, that the operation of the latter is chemical rather than mechanical, and depends on the fact that many vapors of low boiling point are readily absorbed by water, but can be separated again by the application of heat to the mixed liquid, in this case, aqua ammonia.

The functioning of the various parts of the absorption machine is as follows:

The ammonia generator is equivalent to the discharge stroke of the piston in a compression machine, steam being admitted to the generator coils, to cause the solution of ammonia and water to boil and vaporize, creating a pressure to force the vapor in the ammonia condenser to liquefy.

Reasons For Analyzer

An analyzer is used in connection with the generator for several reasons. First, to heat the cold incoming aqua ammonia to the generator with the hot ammonia vapor ascending from the generator, the incoming aqua passing over a series of cast iron trays, coming in direct contact with the hot ammonia vapor from the generator, as in a feed water heater, thus saving a great quantity of steam in the generator. Second, to condense a great portion of the water vapor entrained in the ammonia vapor, by coming in contact with the colder strong aqua ammonia solution, incidentally enriching both the ammonia vapor and the strong aqua, and at the same time removing the greater portion of the entrained water vapor.

The dehydrator or rectifier is for the purpose of removing the remaining water vapor entrained in the ammonia from the analyzer. It is provided with a trap which catches the condensed water vapor, and returns it to the generator, while the now practically pure anhydrous ammonia vapor passes on to the ammonia condenser to be liquefied. The ammonia condensers are of the same type as with compression machines. The pure ammonia vapor from the dehydrator is condensed and conveyed by gravity to the ammonia receiver. From the receiver the liquid ammonia is fed into the evaporating system, which is identical with that of a compression system except that a purging or pumpout line is connected to the lowest point.

Frees System of Water

This purge or pumpout line connects the evaporating system to the aqua ammonia pump and the absorber, and is for the purpose of pumping the contents of the system into the absorber or generator, in case a quantity of water has collected in the evaporator.

The absorber, from which this type of machine derives its name, acts in the same capacity as does the suction stroke of a compressor. Water has a great affinity for ammonia, one part being able to absorb approximately seven hundred parts of ammonia, therefore, the weak aqua ammonia from the generator meets the vaporized anhydrous ammonia from the evaporating system at the absorber, the weak aqua quickly absorbs the vapor, causing it to collapse, inducing a suction similar to that of a compressor.

The absorbing of the vapor by the weak aqua ammonia forms the strong aqua solution, which overflows from the absorber into a strong aqua tank, which acts as a reservoir for the aqua ammonia pump.

The aqua ammonia pump discharges the strong aqua ammonia into the generator after passing through the exchanger.

The exchanger is one of the refinements added to the absorption machine in recent years. The hot weak aqua ammonia from the generator exchanges or transfers its heat to the cold strong aqua ammonia from the absorber on its way to the generator, heating the strong aqua to within approximately 40 deg. F. of the temperature of the generator, and at the same time cooling the weak aqua on its way to the absorber, hence, the exchanger acts like a boiler feed water heater. It saves steam in the generator, and saves cooling water on the weak aqua cooler and absorber.

The weak aqua ammonia after leaving the exchanger is further cooled in a weak aqua cooler, so as to get the solution as cold as possible. The colder the weak aqua ammonia is on entering the absorber, the greater affinity it will have for the gas from the evaporating system.

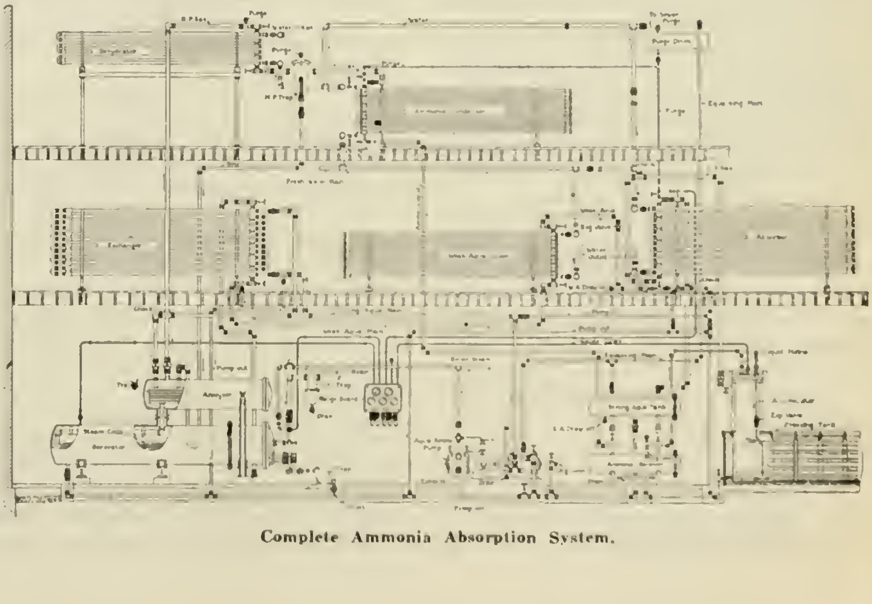
The various parts of an absorption machine are built in a number of types, such as double pipe, atmospheric, shell-and-tube or shell-and-coil types.

The type of apparatus preferred depends on the locality, the atmospheric conditions, the temperature and kind of cooling water available; however, the double pipe and atmospheric types are considered most efficient, and are most popular.

Operation Hints

The operating engineer should familiarize himself with the properties of aqua ammonia, its relations between boiling points at different strengths, temperature and pressure, as is necessary in the case of anhydrous ammonia, water, etc. Mollier's data are used entirely by the writer in designing and operating absorption machinery.

From these curves have been com-



Complete Ammonia Absorption System.

---

*Extracts from a paper read at a meeting of the National Association of Steam Engineers in Brooklyn, N.Y.

piled tables for the convenient use of the operator enabling him at a glance to determine the strength the strong aqua ammonia should have when leaving the absorber under any temperature and pressure used in practice. A second table shows him to what strength the strong aqua will be boiled in the generator when operating with different steam and ammonia temperatures and pressures.

In order to show how these tables will assist in the operation of an absorption machine, we will assume a plant supplied with 70 deg. F. cooling water. It is desired to operate the evaporator with 15 pounds gauge ammonia pressure (O degrees F. temp.).

With 15 pounds pressure the absorber pressure will be 2 to 3 pounds less, say 13 pounds gauge pressure.

Assume that the 70 deg. F. cooling water first enters the condenser, and upon leaving it enters the absorber at 80 deg. F., the strong aqua leaving the absorber at 10 deg. F. higher than the cooling water entering it; this would give the strong aqua leaving the absorber a temperature of 90 deg. F.

By referring to the table, we find that at 13 lb. pressure and 90 deg. F. temperature, the strength of the aqua ammonia leaving the absorber would be 37.2 per cent., or 30 deg. Beaume, which is the strength at which the aqua ammonia would start to boil under these conditions. If it were stronger, the absorber pressure would have to be raised, which, in turn, would raise the pressure and temperature in the evaporators.

Strength of Solution

Assume that in the generator approximately 6 per cent. of the ammonia is boiled out of this strong solution, what should the steam pressure be on the generator and what strength of weak solution would result?

With 70 deg. F. cooling water going to the condenser, we could expect a head pressure of 145 pounds gauge. With this head pressure, and five pounds steam pressure, the ammonia in the generator would boil until it reached a strength of 30.8 per cent., or 26.7 deg. Beaume; after it reaches this strength all boiling will cease under these conditions. If a lower strength is wanted, the steam pressure on the generator would have to be increased.

Knowing the strength of the aqua ammonia, it is necessary to know how much of the strong aqua must be circulated to produce one ton of refrigeration. In order to determine this, it is necessary to arrive at the quantity of anhydrous ammonia that the generator must boil off to produce one ton of work in the evaporator. This may be found by the following equation:

$$\frac{200}{R-(t-t_1)\ x\ s} = \text{pounds } NH_3 \text{ per min.}$$

per ton refrigeration.

200 = Btu per minute per ton refrigeration.

R = Heat of vaporization at evaporator temperature.

t = Temperature of condensing pressure.

t_1 = Temperature of evaporator.

s = Specific heat of ammonia, 1.1.

Using Goodenough and Mosher ammonia tables, the generator would have to produce, under the conditions mentioned,

$$\frac{200}{572.5-(82.3+0.5x1.1)} = 0.4152 \text{ lb. an-}$$

hydrous ammonia per minute per ton of refrigeration.

To produce one pound of anhydrous ammonia use the following equation to determine the amount of strong solution circulated,

$$\frac{100 - W}{S - W}$$

in which

W equals per cent. weak and S equals per cent. strong solution; therefore, we have in this case,

$$\frac{100 - 30.8}{37.2 - 30.8} = 10.81 \text{ pounds of 37.2 per}$$

cent. aqua.

> **An "old fogy" is a man who has ceased to accept new thoughts. And unfortunately some men show symptoms of "old fogyism" at the age of twenty-five. The question is important because the disease is a prevalent one and a menace to every industry. The man who ties the operation of his power plant down to inefficient methods and hampering limitations, who, by snap judgment, condemns any new device or method, without thorough investigation, does a tremendous injustice and hampers his own work.**

The number of pounds of 37.2 per cent. aqua circulated per ton refrigeration would then equal,

10.81 × 0.4152 = 4.49 pounds.

The specific gravity of 37.2 per cent. aqua is 0.875. Therefore, one gallon weighs 0.875 × 8.33 = 7.29 pounds, and the quantity circulated per minute per ton refrigeration is $\frac{4.49}{7.29}$ = 0.616 gallon.

Hence, in a 100-ton refrigerating plant, the ammonia pump would have to circulate 100 × 0.616 = 61.6 gallons.

Assuming that the capacity of the aqua pump is 5 gallons per revolution, it would have to operate at $\frac{61.6}{5}$ = 12.3 r.p.m., provided the cylinders were entirely filled; however, as the pump is not 100 per cent. efficient, it is customary to add 15 to 20 per cent. to take care of slippage.

Fully Charge Machine

The absorption, as well as any other type of refrigerating machine, will not operate satisfactorily if it is undercharged, therefore, the operator should at all times see that his machine is fully charged. By this we mean that the ammonia generator should never show an aqua level below the steam coils. The normal level should be from 1½ to 2 inches above the top of the coils, otherwise the full benefit of the pipe surface is not obtained.

The exchanger, weak aqua cooler, and absorber, if a "wet one," should be filled, and the strong aqua tank should be one-third to one-half full. If the absorber is of the dry type, a liquid level gauge is provided which should show a level well up in the glass.

In normal operation, the anhydrous ammonia receiver should be from one-third to one-half full, and the evaporating system should have sufficient ammonia in it to cause the vaporized ammonia to leave the evaporator with a superheat of not over 5 deg. F.

Aqua ammonia purchased commercially contains not more than 29.4 per cent. of ammonia, or 26 deg. Beaume, therefore, when higher operating strengths are required, it is necessary to add anhydrous until the aqua acquires the desired strength.

If the operator knows the number of pounds of aqua required to charge his plant it is easy to determine the amount of anhydrous required to raise the strength of the commercial 29.4 per cent. aqua to the strength used in normal operation by the following equation:

$$\frac{A\ (S\text{-}W)}{100 - S} = \text{pounds of anhydrous am-}$$

monia to strengthen A pounds of aqua to S.

A = pounds of aqua in system.

S = strength to which it is desired to increase strong solution.

W = the initial strength of aqua.

If a machine contains 10,000 pounds of aqua having an initial strength of 29.4 per cent., and it is desired to increase the strength of 37.2 per cent., there would be required

$$\frac{10{,}000 \times (37.2-29.4)}{100 - 37.2} = 1{,}236 \text{ pounds}$$

of anhydrous ammonia.

An Important Point

One of the most important points in the operation of an absorption machine is to see that the ammonia vapor leaves the dehydrator or rectifier at the proper temperature, for on this will depend the purity of the ammonia entering the condenser and finally the evaporating system.

If the vapor is allowed to leave the dehydrator too hot it will contain quite a quantity of water vapor, which should have been condensed in the dehydrator. This water vapor will enter the condenser with the ammonia, where it will be condensed, and finally be carried over into the evaporating system, where it will collect until the quantity becomes so great that the efficiency of the evaporating system is very much impaired, and that will necessitate pumping or purging out. This causes a loss of time.

The temperature of the gas leaving

the dehydrator should be from 15 to 20 deg. F. higher than the temperature due to the condensing pressure, never higher than 20 deg. F.; for instance, if the condensing pressure is 145 lb. gauge, the temperature due to this pressure is 82.5 F. The gas leaving the dehydrator should then be 97.5 deg. F. to 102.5 deg. F., not over the latter figure. The operator should keep close watch on this part of his machine.

Make Fresh Start

Should the evaporating system become filled with sufficient water to impair its operation, it must be pumped or purged out, and a fresh start made. A pipe connection for this purpose is usually provided, leading from the lowest point of the evaporating system to the absorber.

The operation of pumping out the evaporating system is very simple, and is best done in the following manner:

Close main valve in suction line.

Close liquid expansion valve.

Open valves in pumpout or purge line.

Allow balance of plant to operate as it usually does, except that it is sometimes necessary to slightly increase the speed of the ammonia pump and reduce the steam pressure on the generator.

In starting to purge the absorber and evaporator, the gauges may show a pressure very much higher than they do in normal operation, however, this will soon start to drop, and will continue to drop as the evaporator empties, until the pressure gauges show 0 pounds.

When zero pressure is reached, the evaporating system may be considered empty. The operator should then close the pumpout or purge valve, after which he opens the expansion valve slightly to create a pressure on the evaporator, and finally opens the main suction valve very slowly, after which the machine is again in normal operation.

During the process of pumping out, the anyhdrous ammonia that was in the evaporator is stored in the receiver and other parts of the machine. It must be returned to the evaporator as quickly as possible if work is to be done.

Keeping Machine Free

Another very important point in operation is to see that the machine is always kept free from foreign gases. The presence of these gases will very materially affect the tonnage, as they take up space in the coils, more particularly in the ammonia condenser and the absorber, reducing their effective surface.

In well-designed machines there should be a purge connection leading from the ammonia condenser to the absorber. The contents of the condenser can then be purged through this line into the absorber. By this means the ammonia will be absorbed, and any foreign gas can be purged from the absorber to the atmosphere.

Purging the Absorber

In purging the absorber to the atmosphere, a connection leading from the top of the absorber into a pail of water should be provided. If on opening the absorber purge valve foreign gas is present, bubbles will appear on the surface of the water. The purge valve should be allowed to remain open until all bubbles cease to appear on the surface; when they no longer appear, one can be sure the absorber is free of foreign gas.

The operator should open the purge valve on the absorber at least once a day to determine if gases other than those of ammonia and water are present.

The presence of these gases is revealed by the pressures on the various gauges rising above normal, the temperature in the evaporator naturally rising also, consequently the desired temperature cannot be maintained in the evaporator and other parts of the machine.

Under-capacity of an absorption machine can usually be attributed to one of the following causes:

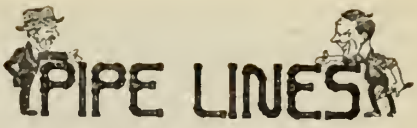
1. Under charge of ammonia.
2. Inadequate circulation of ammonia. The pump valves may be in bad condition.
3. The evaporating system may need pumping or purging out—contains too much water.
4. Condenser or absorber needs purging of foreign gases.
5. Insufficient water supply.
6. Condensers, dehydrator, weak aqua cooler and absorber may be dirty on the water side—remove the scale or dirt, as it is an insulator preventing the water from taking up the required amount of heat.
7. Steam pressure fluctuates. This must be kept steady on both the generator and pumps.
8. Sluggish brine circulation. The pump valves may be in bad condition.

Should trouble occur, look into the above causes for under-capacity and you will nearly always detect the trouble.

The conditions for operating an absorption machine differ in each case, depending upon the temperatures required and the water supplied. No set of rules can be given that will apply to the operation of all machines, therefore, for each installation the operating conditions must be arrived at as explained in this article.

Dickinson Dye Works, 986 Dufferin St., Toronto, are installing an underfeed stoker of the Jones type as well as a feed water pump and heater. George J. Soucy is the engineer in charge of the work.

Laughlin's Products Ltd., of Stratford, makers of Imperial oil burners, have issued, through their sales office at Welland, a booklet, Liquid Fuel, describing the origin and history of oils; the grades and the heat content of each; oil storage and handling; five methods of burning fuel oils, and some valuable hints for securing maximum efficiency in the power house.



UNCOVERED IN ANY OLD SPOT

Engineers well know it has been said:
"It takes a pull to get ahead!"
But lay aside those words as "bull"
It takes a head to get a pull.

A pound of pure carbon requires 11.6 lb. of air for complete combustion. As coal is not all carbon, but contains a variety of ingredients, all of which vary in different coals, from 20 to 40 lb. of air per pound of coal is required. The difference between the theoretical quantity and the quantity practically needed is the "excess air," as it is called. "Too much excess air," then, means more than the quantity practically needed.

* * * *

A power plant problem properly stated is one nearly solved. It is often an aid in the solution of a problem to suggest its opposite; analogy encourages suggestions.

* * * *

A boiler should be considered as composed of two distinct parts—a furnace wherein fuel is burned to produce heat, and a shell or vessel containing water to absorb the heat produced. The furnace efficiency may be the maximum obtainable and yet the overall efficiency of the boiler be low because of scale and soot on the heating surface; the heating surface may be clean and capable of the most rapid transfer of heat, yet because of unsuitable fuel, plugged air spaces in the grate, leaky furnace walls and doors, the overall efficiency may be low.

* * * *

And so the wise men in the east have decided to resume digging coal and making steel.

* * * *

The sampling pipe through which passes the flue gas collected for analysis should be placed in the most active part of the gas flow. A good way to tell that you have the pipe in the right place in the uptake at the damper on the boiler side is to move it in and out across the gas path, analyzing samples collected at each position; the point where the quality of the gas varies most widely in a given time is the correct place for the sampling pipe.

* * * *

If an expert gambler can stack the cards, what can a good smoke stack?

* * * *

To reduce the maintenance cost of furnace lining in stoker-fired, forced-draft boilers, a high-grade firebrick is used up to the fire line; a bauxite brick is commonly employed for this purpose.

Easy Engineering Lessons in the Power House

By M. BARRY WATSON, B.A.Sc., M.E.
Director of Engineering, Central Technical School, Toronto.

FRICTION is defined by Rankine as "that force which acts between two bodies at their surface of contact so as to resist their sliding on each other."

The above definition does not seem to the writer to be quite complete because we have friction entering into the rolling of one body over another as well as sliding. These kinds of Friction may be classified as Sliding Friction and Rolling Friction.

Friction may act both while bodies are at rest or while they are in motion. For example a man may stand still on a sloping sidewalk because of the friction between his boots and the surface of the sidewalk. However, if the sidewalk is covered with ice, he will be unable to stand still because there is now very little friction between his boots and the ice.

We also know that when a body is in motion friction is constantly trying to stop the motion. The force required to start a body moving over a surface is called the Friction of Rest, while the force required to keep it moving once it has started is called the Friction of Motion. These two kinds of friction are not the same, as will be shown later.

Causes of Friction

Friction is caused by the roughness of the surfaces in contact and by the softness of the surfaces. We are unable to produce a perfectly smooth surface, although we can come very close to it. Looked at through a high power microscope the edges of two ordinarily smooth surfaces in contact would look something like Figure 1. The real positions of contact being a series of points where the slight irregularities of the surfaces happen to touch.

If a few points that first touch are not strong enough to support the weight to be carried, some of the points will be crushed, bent or driven into the other surface until sufficient other points come into contact to support the load. It will be clearly seen that if one of these surfaces is slid over the other, work must be done in bending or breaking off some of these points of contact or else in raising the upper surface sufficiently for its high spots to pass over the high spots on the lower surface.

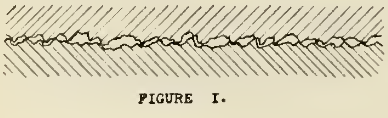

FIGURE I.

An example of the friction when the high spots break off is in the sandpapering of a piece of wood. Of the points of contact bending over, is in a steel shaft running dry in a babbitt bearing sufficiently slowly to be kept cool, the babbitt will be found to be dragged around in the direction of the motion of the shaft. It is doubtful if we ever have a true example of the case of the one surface being raised sufficiently to clear the high points of the other, because a certain amount of wearing away or smoothing down of the surfaces always occurs.

Softer Than Other

When one surface of a pair is softer than the other, friction may be caused by the harder one sinking into the softer as shown in Figure 2. Of course the greater the pressure between the surfaces the greater the distance one surface will sink into the other. This might well be illustrated by a weight on a piece of rubber. It is clear that if the top body in Figure 2 is slid along on the lower body, the edge "A" is continually digging into the lower surface and either cutting it or compressing it causing friction. This explains the fact that the friction between hard surfaces is less than that between soft surfaces of equal smoothness. This fact is well illustrated by the difference in power required to move a wheelbarrow over a concrete floor and over soft earth.

Rolling friction can be understood to be caused in the same way, because under a microscope, even a good roller bearing and its race would give an appearance similar to the cleated driving wheel of a traction engine riding on a stone road.

In the case of the traction engine it is easily seen that force is necessary to raise the whole weight of the machine over each cleat on the drive wheel or over each high spot on the road, also to press the cleats into the road surface or even to break up some of the stones of which the road is built, as well as to wear away part of the surface of the driving wheel. All these things take place when any one surface rolls on another.

Coefficient of Friction

The force required to move a body along a horizontal surface, divided by the weight of the body, is known as the coefficient of friction, and is commonly denoted by "f". This coefficient is not an exact constant for any material. The value may be 0.28 for wrought iron sliding on a piece of cast iron, while a piece of steel may give a value of 0.3 on the same piece of cast iron.

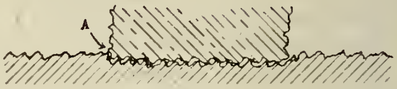

FIGURE II.

Also the fineness to which the material is smoothed will influence the value of this coefficient, as will the elasticity, hardness and toughness of the material, as on these properties will determine whether the high spots will break off, bend over permanently or bend over and spring up again. Thus numerical values for the coefficients of friction of various pairs of materials are of little real value, except as a rough guide of what to expect under certain conditions.

In the case of fibrous materials such as brake linings, fabrics or asbestos, it is found that if the weight is distributed over a larger surface, thus giving a smaller pressure per unit of area, the coefficient of friction is increased. This may be because the small projections on the surface are not squeezed down so tight and therefore catch against those on the other surface easier. Thus it would appear that if the unit pressure is increased the coefficient of friction of fibrous material would be lower. This is found to be the case, but does not apply to metals or non-fibrous materials. Because of this property, brakes with fabric lining such as on winches, motor cars, etc., should be made with as big surface as possible in order that they may exert their greatest friction while working at low pressures.

Decreased by Speed

The coefficient of friction is decreased by an increase in speed or relative velocity between the surfaces. This may be explained by the fact that the projections which have been bent over or squeezed in by passing over projections on the other surface do not have time to spring back to their full size or normal position again before they strike more projections to be passed over and therefore they do not have to be bent over so far or compressed so tightly as they did at a slower speed thus requiring less expenditure of energy. Or in the case of the harder materials, if one body is raised up to pass over irregularities in the other surface it does not have time to fall back all the way into the depressions before it strikes the next projections, or as one would say in slang, it has such high speed it "just touches the high spots."

This applies equally to sliding or rolling friction. The coefficient of friction increases as the relative velocity between the bodies gets slower until it is a maximum when the surfaces are stationary, or in other words the friction of rest is greater than the friction of motion.

The friction of rest between metals when dry is usually between 0.2 and 0.4. An example is the coefficient of friction of steel tires sliding on steel rails which has been found to be about 0.11 at ten miles an hour and only about 0.04 at fifty miles an hour. This explains why brakes give a much greater stopping effect at low speeds than at high speeds.

Fluid Friction

As well as the friction of solids sliding or rolling one on another, there is a form of friction where a layer of a fluid flows against a solid surface, or where different parts of a fluid flow with different speeds, one layer thus rubbing against another.

We know that there is such friction because it requires power to make fluid flow through a pipe; also the velocity at the centre of a pipe or a river is greater than near the sides because of the friction against the sides. Fluid friction may be caused by the supposed molecular structure of the fluid, in which the molecules must rub against or bump over each other in some way.

The friction between a solid and a fluid appears to be greater than between two layers of a liquid; a possible explanation of this phenomenon will be given after we look into the action of fluid friction.

Fluid friction is, unlike solid friction, independent of the pressure on the fluid. This is possibly because a fluid exerts the same pressure at all positions and in all directions, thus there is no way by which it can compress part of the container more than the other as a solid is shown doing in Figure II.

Fluid friction is somewhat similar to the friction between fibrous surfaces in that it is greater if the area against which it rubs is greater. This may be illustrated by say a gallon of water in a half inch pipe touching more surface than if it were in a six inch pipe, thus the friction loss in moving water through a small pipe is greater than in a larger one.

Velocity of Flow

In respect to velocity of flow, fluid friction is just the reverse of solid friction, in that the coefficient of friction increases with the velocity. At low speeds the friction increases very nearly in the same ratio as the speed, but at medium and high velocities the friction increases as the square of the speed. This fact will be made use of later on in explaining the phenomenon mentioned above.

The friction of a fluid does not depend on the kind of solid against which it flows, but only on the roughness of its surface. The friction of dense or heavy fluids is greater than that of light fluids. It is also dependent on the viscosity of the fluid, which is a measure of the speed with which it will flow or change its shape. For example, gasoline has very little viscosity while cylinder oil is quite viscous, especially if cold.

In order to investigate the way in which fluid friction acts, let us assume a layer of fluid between two flat surfaces, one of which is moving with respect to the other at the rate of say 125 feet per second. This might be illustrated by the cross head of an engine sliding on the guide. Figure III represents such a condition as seen under a microscope.

The surfaces are seen to be not actually in contact with each other but separated by a layer of fluid. It is likely that all the fluid or oil which is below the tops of the projections on the surfaces of the solids will remain where it is.

For a starting point let us assume that with a velocity of one foot per second, each unit area produces one unit of friction. We will consider one unit of area. We will first determine the amount of friction generated if all the fluid above the line marked C-C travels at 125 ft. per sec. and all below that line stays still. The relative velocity at the surface of rubbing will be 125 ft. per second, and since the friction varies, as the square of the speed, friction will be 125x125, equals 15,625 units.

Let us next assume that the fluid breaks up into six layers instead of two. That above line A-A will be going at 125 ft. per sec. That between A-A and B-B at 100 ft. per sec. and so on. Thus there will be five surfaces of contact at each of which the relative velocity will be 25 feet per sec. The friction at any one of these surfaces will then be 25x25 equals 625 units per unit area. Therefore the total friction will be 625x5 equals 3,125 units, which is much less than in the first case assumed.

Should Speed Vary

It is seen from the above that there will be very much less friction if all parts of the fluid do not travel at the same speed, and we find in practice that the fluid automatically divides itself into a very large number of very thin layers all moving with very low speeds with relation to the layers in contact. In this way the friction of a fluid is apparently much lower than that between the fluid and the solid, and it automatically maintains itself at this minimum value. This explains why the velocity in the centre of a pipe is greater than half way to the walls. It also gives us an easy way of cutting down friction by means of lubrication, provided we can keep the layer of lubricant between the surfaces moving.

Lubrication and lubricants will be discussed in a future lesson and the above material will be of value in understanding some of the points brought out.

A. J. Nesbitt, head of the firm of Nesbitt, Thomson & Co., Montreal, has taken over the Ottawa & Hull Power Co., the largest concern wholesaling power in the Ottawa and Hull district.

M.D.E.A. Notes

At a meeting of the Montreal and District Engineers' Association in the Royal Arcanum Chambers, 592 Union Avenue, Montreal, on July 27, H. Wright was unanimously elected Doorkeeper. Three new members were initiated, and applications received from three others. Lectures have been given the Association recently by Mr. Carter of the Canadian Ingersoll-Rand Co., and A. Aubin of the Canadian Comstock Co., and arrangements are now being made by the Educational Committee for the August 10 meeting. The membership of the Association is now over 150.

The officers appointed for the current term are: Past President, A. Kastello; President, W. G. Forbes; Vice-President, A. Hall; Secretary, I. McIntyre; Financial Secretary, A. J. Jones; Treasurer, W. H. Rose; Conductor, J. Dodds; Doorkeeper, H. Wright; Trustees, F. Stockden, J. A. Alder, and A. Reid.

U.C.C. of E. Notes

The Universal Craftsmen Council of Engineers are holding their 21st annual convention at the Powers Hotel, Rochester, N. Y. The convention, lasting four days, August 7, 8, 9, 10, 1923, includes an exhibit of power plant machinery, electrical equipment, accessories and supplies under the direction of the Universal Craftsmen Council of Engineers, being held in the banquet hall of the hotel.

Many events and features of interest have been planned for the entertainment of exhibitors, delegates and visitors to the convention.

Trade Catalogs

The Combustion Engineering Corporation, Limited, Bank of Hamilton Building, Toronto, have issued a condensed Canadian catalog, describing briefly the various lines of power plant equipment made and sold by them.

The type E, Coxe Travelling grate, Frederick, type K, and Green chain grate stokers are described, as well as a new type of self-contained travelling grate stoker, in which fans, motors, and the driving mechanism, are a part of the stoker. Other equipment shown includes the Quinn fuel oil burner, Lopulco pulverized fuel systems, Green cast-iron hoppers, Combusco water seal ash conveyor, Custodis chimneys, Detrick flat suspended arches, Uehling CO_2 recorders, and recording instruments and Arrow ash hoppers and ash grates.

Economies of Reducing Valves in Power Plants

By H. H. SHUGART*

Pressure Regulators Should be Given Care, Usually Accorded Automatic Machinery Functioning Continuously, to Attain Best Operating Results

IT HAPPENED almost in antiquity. Making his annual journey from his estate in a remote province of Egypt up towards Cairo, Al Hasson, a man of substance and great learning, saw a sight that filled him with astonishment, something entirely new. It was the first crude water-wheel driven by the waters of the Nile, with which men were grinding their grain. He was so taken up with the device that he returned home and forthwith set about the construction of a similar wheel, instructing his slaves intimately in the details. The wheel was finally completed and set in position, but, to his great chagrin, did not work. The stream in which it dipped its paddles was too small; the flow of water insufficient.

He cast about for a solution to the problem, but after much fruitless speculation sent for Mech-Anic, who had built the water-wheel on the Nile. Mech-Anic attacked the problem with gusto. First he dammed the stream. Then instead of having the water flow under the wheel, he caused a conduit to be made that directed the flow of water over the top of the wheel.

But the conduit was too large. The rush of water drove the wheel too rapidly, and to boot, soon exhausted the reservoir. So bethinking himself further he provided at a certain point in the conduit a controllable stop, or valve, by means of which he lessened and controlled the flow of water. Thus the problem was solved. The wheel traveled at the correct speed. It ground the grain properly. And the water was so conserved that there was power enough to do in a day what many slaves had failed to do in a week.

This man, therefore, in a simple way restrained the flow of large volume of fluid; reduced a higher pressure to a lower pressure; kept that low pressure constant (regardless of the amount necessary to drive his wheel, and regardless of change in the higher pressure). It is true that he had to have a man manipulate his simple valve constantly in order to do it. But the big point is—that by means of the valve he did something that could not otherwise properly be done.

Conserves Power

What has this to do with reducing valves? Let us see. A good pressure reducing and regulating valve (1) reduces a higher pressure to a lower pressure; (2) holds that lower pressure constant regardless of changes in the higher pressure; (3) holds that lower pressure constant regardless of changes in the demand on the low pressure side; (4) conserves, or saves power; (5) does something that could not otherwise properly be done; (6) does it automatically.

"But," you may ask, dispossessing yourself of all knowledge in order to get to the bottom of the subject, "why reduce the pressure? If the greater the pressure, the greater the power; why reduce power?" There are many answers.

Eliminating Waste

Suppose your heating system requires steam, as the average system does, at a pressure no greater than five pounds. And suppose you have no exhaust steam with which to supply this demand. You are compelled to use live steam from your boilers at, say, 125 pounds pressure; but instead of delivering it wastefully, and often dangerously, at this pressure, you use a reducing valve to cut the 125 pounds down to five pounds pressure.

Or assume that you do have a steam supply taken from the exhaust of engines and other equipment, but this supply proves at times inadequate for the heating load. Live steam must then augment the exhaust steam, and a reducing valve cuts down the pressure automatically, delivering it into the exhaust header at the correct low pressure. In both these cases, the small reducing valve investment eliminates the necessity of installing a low pressure boiler to carry the heating load.

A Second Purpose

Now to the second purpose of these valves. The reducing of pressure having been justified, why hold the low pressure constant regardless of changes in the high pressure? Consider this example. Boiler pressure varies. If a globe, or stop valve is set so as to cut 150 pounds down to 90 pounds pressure, an increase above 150 pounds will mean an increase above 90 pounds. In many cases, particularly in process work, this increased pressure results in financial loss.

A specific temperature is correct for the process, a higher temperature is either unrequired or damaging, and an increased pressure means a proportionate increased temperature. A good reducing and regulating valve, being operated or controlled from the low pressure side, maintains the correct low pressure regardless of either an increase or decrease in the initial pressure, provided, of course, the high pressure does not fall so low that it almost equals the desired low pressure.

A Third Purpose

The third declared purpose of a good reducing and regulating valve is holding the lower pressure constant regardless of change in demand on low pressure side. In practically all process work, quality production depends largely upon the temperature maintained in the cookers, moulds and other apparatus which are usually heated by steam. The desired temperature is, as a rule, maintained by keeping a constant steam pressure in the heating jacket or coils corresponding to the temperature desired. The demand for steam varies widely on these services, for when the moulds are filled with cold material to be cooked or cured, the demand for steam is very high as, under these conditions, the jacket or steam coils, condense it rapidly. After the material is warmed up, the steam demand is decreased, and after the apparatus is brought up to the proper temperature, the steam demand is slight indeed.

Retards Production

At the beginning of the process when supplying steam to cold apparatus, because the demand is excessive, the inferior reducing valve may permit the low pressure to drop considerably below the predetermined pressure. This wastes time and retards production. A good reducing valve answers the peak demand with more pressure. That is, more pressure through the valve in order to compensate for the drop in pressure in the apparatus due to the enormous quantity of steam consumed and the great condensation, holding the predetermined low pressure constant in the apparatus regardless of high demand and holding it constant at that pressure after the demand has fallen off.

The fourth reason for using reducing valves to conserve or save steam. If pressure is power, and all that is required to efficiently operate a given piece of equipment is a certain pressure, a high pressure is obviously wasteful—so many pounds of steam gone for nothing, so much coal, so much money.

Take for example such a common thing as a steam jet ash conveyor. The nozzle is designed to give you 100 per

Prolonging Valve Life in the Boiler Room

By ARTHUR MURPHY*

A Description of the Types in General Use in the Steam Plant Together with Hints as to Their Selection and Care in Their Maintenance

THE function of a valve is to control the flow of a fluid, the nature of the liquid or gas and the quantity handled determining the type best suited for the work. In the power plant the types generally used include globe, angle, gate, blow-off, safety, non-return, automatic stop, and pressure reducing. The recent tendency toward large units and automatic control has also brought about the development of remote control of main valves.

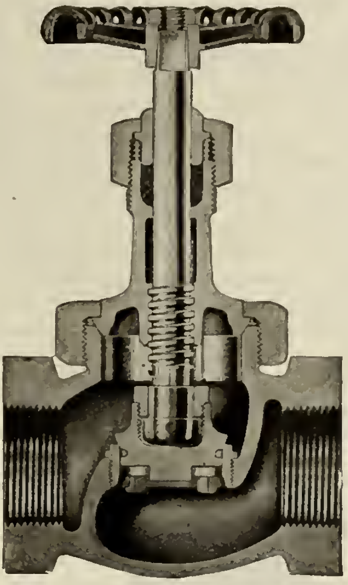
It is proposed in this article to describe the better-known types and emphasize points for the engineer to observe to prolong the life of the valves in his plant.

Renewable Disc

The globe valve is the most common of all types and is so well known to engineers that it will suffice to say that savings can be made by a little care in replacing worn seats or discs instead of throwing the valve away and buying a new one. The majority of valves of this type are made with renewable valve seats and discs that can be quickly replaced by sliding from a groove. The disc in the small globe valve is frequently made of a rubber compound, soft enough to conform to any slight irregularity in the seat. The proper disc should always be used. One intended for cold-water service cannot be expected to withstand the temperature of high-pressure steam. This point is often forgotten when running new pipe lines and making use of equipment on hand. Some of the newer types are made with a shoulder on the stem so that they may be packed under pressure when wide open.

The gate valve is an all-metal valve with metal-to-metal contact at the seat. As this valve when wide open presents practically a straight passage, the frictional loss in it is small. This type finds favor, especially in the larger sizes, for hydraulic work. It is advisable in such sizes to have both the seat and valve disc renewable. In the smaller sizes a valve reseating tool will aid the engineer in keeping the valve tight. Care must be taken when refacing the disc and the seat to secure the same angle on each, or the leak may be worse than before.

When used for superheated steam the body should be of some material other than cast iron.



Type of Globe Valve.

For protecting engines and turbines from overspeeding in case of failure of the governor and to protect firemen and others from scalding in case of a tube failure, automatic stop and non-return valves were devised. The valve disc is so balanced that the normal flow of steam will not operate it, but any abnormal rush or reversal of flow will cause it to close at once.

This type of valve is in common use on steam boilers between the header and the boiler. In case of a tube failure or sudden drop in pressure in the boiler, the friction of the steam through the valve causes the disc to close, in this way preventing any steam other than that in the crippled boiler from escaping and adding to the danger.

Another safety feature of the non-return valve is the fact that steam cannot be turned into a boiler which is open for repairs or cleaning to scald any men who may be in it.

The simple non-return valve closes only on reversal of the flow of steam; in others an automatic stop is provided by having a balanced double disc, then either a reversal of flow or a sudden rush of steam in case of a burst header will cause the valve to close, stopping the flow of steam from the boiler.

All boilers when used in a battery should be fitted with non-return valves. In some provinces their use is compulsory.

The Canadian interprovincial regulations require on each main or auxiliary steam outlet from a boiler a stop valve immediately at the boiler, when the working pressure exceeds 100 lb. per sq. in., and when the steam pipe is 2½ in. or over in diameter the stop must be of the outside screw and yoke type.

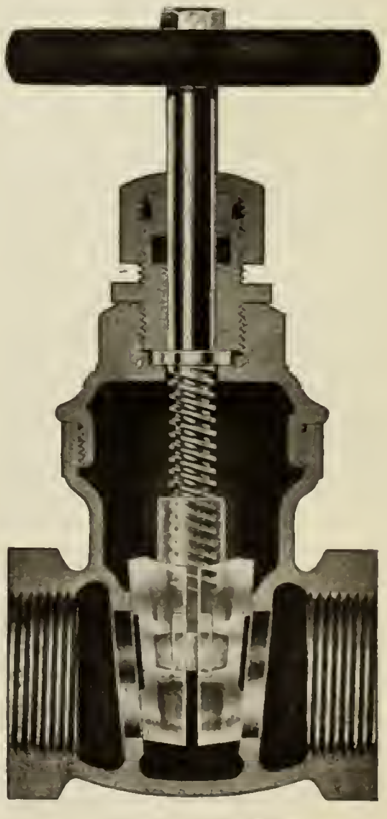
Where two or more boilers are connected to a common main and the pressure is 100 lbs. or over, each boiler must be equipped with an automatic non-return valve of approved design in addition to the boiler stop valve.

Another form of non-return valve is now being made for protecting turbines from back flow of water from a jet condenser containing a balanced check valve which closes when the condenser ceases to operate for any reason and water starts to back up in the main. It is customary to provide a relief valve between the turbine and the automatic non-return valve open to the atmosphere.

Severe Service

It would be difficult for any engineer to devise a more severe test for a valve than that given the blow-off valve on a steam boiler. The service is so severe that no ordinary valve will stand up any length of time, and as a result special designs are used. The valve must be tight under all conditions, any leakage being not only costly but dangerous.

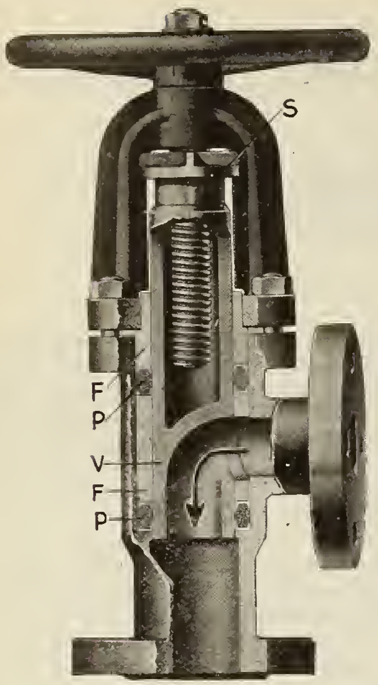
The water from the mud drum or lower part of the boiler passes through



Type of Gate Valve.

---

*Editor, Power House.



Type of Seatless Blow-off Valve.

the valve with high velocity and as it carries dirt, scale and other abrasive materials it causes considerable wear on any part that it comes in contact with, and furthermore when the valve is being closed small pieces of scale often lodge between the disc and the seat.

Eliminate Seats

For these reasons valves with ordinary gate or flat discs and seats are not used, a type in which the water and scale cannot score the seat being favored.

The valve shown in Fig. 1 was designed with these points in view and the fact that in some plants no repairs in over ten years have been found necessary proves that the principle is right.

The valve is shown wide open, presenting a clear passage for the water and scale. To close the valve, the handwheel is turned until the port in the plunger V has passed the corresponding opening in the body of the valve. After it has been closed, the shoulder S on the plunger V strikes the loose follower gland F. A hard turn of the handwheel then compresses the packing P above and below the port, making a tight valve.

The Canadian interprovincial regulations for the construction of steam boilers stipulates that each boiler must be provided with a substantial blow-off pipe and valve or packed cock. The valve or cock shall be extra heavy, of straightway or other approved or registered design, the minimum diameter being one inch and the maximum two and a half inches. Globe and angle valves shall not be used for this purpose. It is recommended that two valves, or a valve and a packed cock be provided at the blow-off outlet of each boiler. A blow-off cock shall be protected by a guard or gland.

In some cases a gate valve is used in place of a cock. Where a valve and cock are used it is customary to put the cock next the boiler and outside of the blow-off valve. If a gate valve is used instead of a cock it is advisable to install it with the stem horizontal, so that the movement of the disc will keep the scale agitated and prevent it lodging between the disc and the seat.

When blowing off a boiler the gate valve or cock should be opened first, then the blowing off operation proper controlled by the blow-off valve; upon finishing, the blow-off valve should be closed, then the gate valve or cock.

A safety valve must first of all be reliable and secondly must have ample relieving capacity. The greater number of safety valves in use in power plants to-day are of the spring loaded, pop type with the valve disc and seat either flat or bevelled at 45 deg. Safety valves should be opened at least once a day, preferably by raising the pressure in the boiler sufficiently high to cause the valve to open, or, if this is not convenient, by lifting the valve from its seat by the lever attachment.

Sometimes this precaution is overlooked, as in the case of a large low-pressure heating boiler in the city of Toronto. The safety valve did not open at 385 lb. pressure when tested by a boiler inspector; fortunately the man in charge did not attempt to open the valve by raising the pressure further.

Valves for Boiler Blow Off.

A leaking safety valve is not only annoying but wasteful and should not be tolerated in any plant. A few minutes' work with a grinding compound will remedy the trouble. The adjustment of the safety valve on a boiler should not be tampered with by anyone unless he has authority to do so; in many provinces this right is reserved for the boiler inspector.

Causes Chatter

An adjusting ring on the valve regulates the amount of blow down or the difference between the relieving and closing pressures. The difference should not be excessive or considerable steam will be lost every time the valve opens; not more than 4 lb. for boilers operating below 100 lb. and 8 lb. for boilers operating over 200 lb. Too small a pressure difference results in chatter.

The relieving capacity should be sufficient to prevent the boiler pressure exceeding 6 per cent. of the normal relieving pressure with it steaming at maximum capacity and with the feed water shut off and all other valves closed.

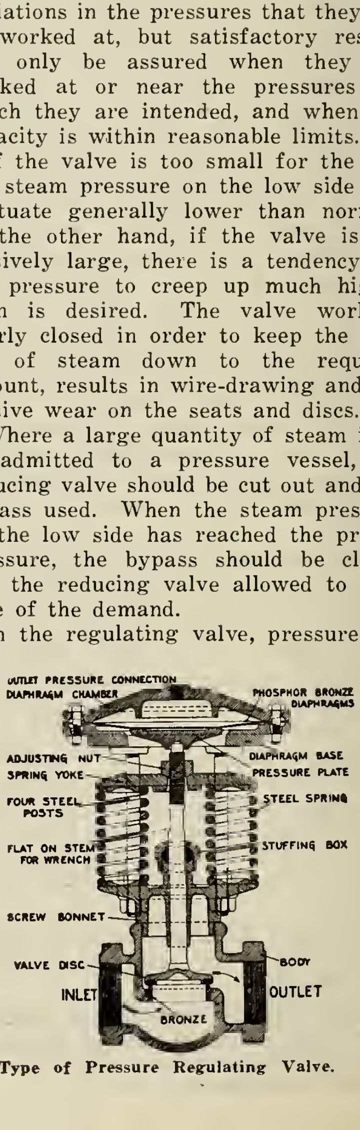
Protect Valve

Pressure reducing valves are in wide use in plants using steam for industrial processes for reducing the pressure from high to lower for the purpose of controlling the temperature; in others, to secure a steady pressure on some machine. The reducing valve in some plants is a continual source of trouble, more especially when used at the end of a long steam line which contains a fair share of condensate. The installation of proper traps and the use of a screen immediately before the valve will save the cost in a short time in repairs and annoyance of frequent shut-downs. A pressure reducing valve should always have a bypass in the line so that the valve can be cut off for inspection or repair and the steam regulated by an ordinary valve of the globe or gate type until the pressure reducing valve is in service again. These valves should be taken apart and cleaned at regular intervals. On valves of this type, the adjustment provides for considerable variations in the pressures that they can be worked at, but satisfactory results can only be assured when they are worked at or near the pressures for which they are intended, and when the capacity is within reasonable limits.

If the valve is too small for the job, the steam pressure on the low side will fluctuate generally lower than normal; on the other hand, if the valve is excessively large, there is a tendency for the pressure to creep up much higher than is desired. The valve working nearly closed in order to keep the supply of steam down to the required amount, results in wire-drawing and excessive wear on the seats and discs.

Where a large quantity of steam is to be admitted to a pressure vessel, the reducing valve should be cut out and the bypass used. When the steam pressure on the low side has reached the proper pressure, the bypass should be closed and the reducing valve allowed to take care of the demand.

In the regulating valve, pressure ad-



Type of Pressure Regulating Valve.

mitted at the opening marked outlet pressure connection acts on the top of a diaphragm and controls the movement of the valve stem and valve disc. An adjusting nut on the stem controls the pressure on the outlet side, giving the required variation in pressure.

When used for controlling the speed of a stoker engine or fan engine, a steam connection from the boiler is made to the top of the regulating valve, then an increase in pressure above that required forces the diaphragm down, closing the valve and reducing the amount of steam admitted to the engine, in this way cutting off some of the fuel or decreasing the speed of the fan.

Check valves in the power house are given hard service, especially when a defective steam pump is used as a boiler feed. The valve closes with a hammer-like blow and if not constructed of the best of materials will in a short time hammer its seat to pieces. A leaky check valve is a menace to efficiency, as the water in the boiler may escape and serious damage result through burnt tubes or sheets.

In one Toronto plant considerable trouble was experienced with the valve on the soot blower after it had been in service but a short time. The valve was installed at the bottom of a length of pipe, with the steam pressure acting against the valve disc. The valve leaked no matter how tightly it was closed.

Shrinkage of Stem

The valve maker was consulted and recommended that the valve be placed in a horizontal part of the pipe line close to the boiler with the pressure acting on the top of the valve instead of against it as in the first installation. When these changes were made, no further trouble was experienced with leakage.

In the first place before the valve was changed water would build up in the leg then leak through to the soot blower. The explanation given was that after the soot blower had been in use and the valve closed, both the valve stem and the seat were hot, water of condensation then collected in the piping above the valve and, since there was no circulation, the valve cooled off, causing the stem to shorten and the disc to shrink away from the seat, leaving a small opening, which though only a few thousandths of an inch was sufficient to start a leak.

With the pressure on the top of the disc and the valve stem kept hot by the steam, the valve remained tight and with only a short length of pipe between the boiler and the valve there was no water condensation to cause trouble.

The life of a valve in the boiler room depends in the first place on the quality and the kind of material used in its construction. The material must not be attacked by the fluid flowing through it. Even the highest grade of brass valve would not last as long as a poor one made of iron when used for ammonia service. For water, the valve should be non-rusting or resistant to corrosion. Cast-iron is not as suitable for superheated steam as cast-steel. Monel metal seats are claimed to stand up to superheated steam better than many other materials.

Special Valve Seat.

The requirements of a good valve may be summed up as follows:

It must be easy to operate the valve, even after it has been idle for some time.

It must not leak.

Wear should be slow but all parts on which wear occurs should be readily replacable, such as valve seats and discs.

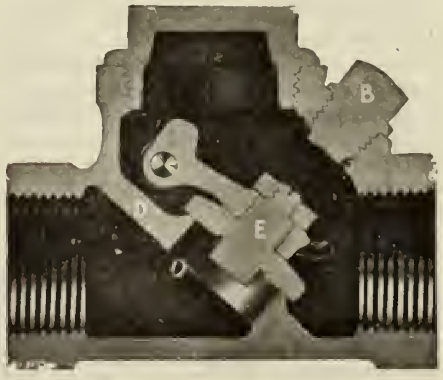
> **The inherently local nature of the generation and use of steam power prevent it from becoming a commodity. The contrary is true in regard to electric power. The characteristic of electric power constituting it a true commodity, the fact that it can be generated in bulk and sold at retail, the ease and flexibility of its transmission to a distance from its point of generation by means which can be extended at will, make natural the centralization of sign. This carbon will not settle out its generation.**

It must be strong enough for the pressures under which it is intended to operate.

The material of which it is composed should be suitable for the service intended.

Workmanship should be good and the external appearance in keeping with the location.

The stem and packing gland should be of a type that makes frequent repacking unnecessary but when required a quick and easy job.

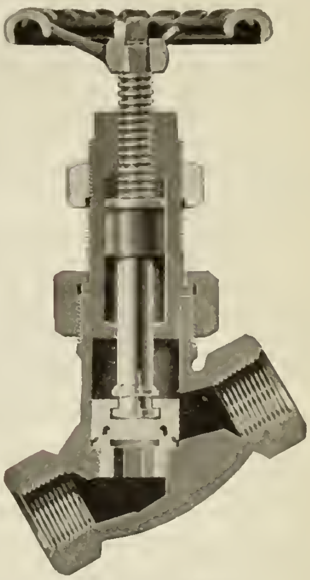


Type of Check Valve.

Frictional losses when used for liquids should be small.

The latest advance in the valve field is the application of remote control. The engineer can appreciate the advantage of being able to control all the valves in his plant by the pushing of buttons located on a central board instead of having to go from valve to valve and close by manual labor. Electricity is the usual source of power for working the valves but compressed air and hydraulic pressure are sometimes used.

When motor operated, the speed of closing can be varied to suit the requirements, large valves as a rule cannot be closed rapidly. A small motor is mounted directly on the valve and the power transmitted to the stem through gears, an automatic stop being provided for the motor for the open and the closed positions.



Type of Y Valve.

Safety valves have blow-down or huddling rings for adjusting the blow-down. If a valve opens at the correct pressure, but does not close until the pressure has dropped, say 5 lb., instead of the usual 3 lb., the huddling ring needs adjustment.

The safety-valve capacity on a boiler should be such that the valve or valves will discharge all the steam that can be generated by the boiler without allowing the pressure to increase more than 6 per cent. above the maximum working pressure or more than six per cent. above the highest pressure to which any valve is set.

An automatic stop valve is just as much a necessary safety device for a boiler as a safety valve. And an automatic valve doesn't cost over 5 per cent. more than an ordinary stop valve of like size. Then considered as safety insurance the investment in a good automatic valve for each boiler is about as much for the money as could be had in most any other way.

Ford to "Burn Coal Twice" in Canadian Plant

New Process to Produce Coke, Benzol, Creosote, Sulphate of Ammonia, Gas and Basic Oils in $500,000 Plant at Ford, Ont.

WILL the farmer of the future fertilize his soil with a by-product of the coal consumed in city factories; will the motorist of the future operate his car with fuel and lubricating oil which is another by-product from the same base; will the factory of the future be designed to operate in conjunction with a new type of power-producing plant, where coal will be made to produce not only heat units but a wide variety of other things as well, such as benzol, creosote, sulphate of ammonia, fuel, gas, smokeless furnace coke and a number of basic oils?

It is an interesting and rousing speculation, and it is nearer to realization than many engineers suppose, for such a plant is now in course of construction by the Ford Motor Co. of Canada, at Ford, Ont., and is the material evidence of the first commercial realization of Henry Ford's much heralded scheme to "burn coal twice."

Ever since it was discovered that soft coal would burn, getting rid of the heavy soot and smoke has been a serious problem, and much time and money has been expended in efforts to find a practical method of disposing of it, even though it was commonly known that the smoke represented valuable properties which the ordinary method of burning soft coal liberated but failed to utilize.

Solution in Sight

That problem, however, may soon be written in the industrial history of a bygone day, for in the new Ford by-product plant, coal will be subjected to an entirely new process of treatment through which many by-products will be recovered before the coal, converted into coke, pulverized and fed into the furnaces by blowers is consumed in much the same way as gas is burned, and the by-products themselves in turn will be converted and consumed to serve a variety of purposes.

The new process is based upon a method of coal distillation which differs from all previous practice in that the coal is distilled at a comparatively low temperature, which makes possible the recovery of "volatiles" which have hitherto been lost because high temperature process ovens only have been used.

The distillation of coal through the application of heat, in an enclosed refractory chamber, in its earliest development, was accomplished in a crude way by the use of the beehive oven, and although the resulting coke was highly valuable for metallurgical purposes, all of the by-products were allowed to escape to the atmosphere.

Erected in France

In the year 1854 the first coke oven permitting the recovery of by-products was erected at Commentry, in France, and this led to the almost universal adoption of this method, as these by-products are the base for all the coal-tar products which are particularly valuable in the aniline dye industry.

The gases arising from coal as the result of low-temperature distillation are primary in character, and their products very closely resemble petroleum, but the character of these by-products changes as the heat increases, so that after the temperature to which the coal has been subjected passed 1350 degrees F., their structure due to the effects of heat, has been converted into an entirely new series of chemical compounds, of which Benzol is the most important. Benzol, when properly treated, is a gasoline substitute of excellent properties, largely used in the operation of automobiles.

Advantage of Low Temperature

The principal point of difference between the products of coal distillation at high temperature as compared with the products of coal when distilled at low temperatures is that by using the latter method a larger percentage of fractions suitable for use as gasoline substances is obtained. In other words, the material arising from the coal is in a gaseous state and on being condensed a greater proportion takes liquid form when cooled, in low temperature distillation, than in high temperature distillation.

After chemical treatment, the available amount of Benzol or Motor Fuel resulting from high temperature distillation will reach a maximum of 4½ gallons per ton of coal treated whereas in low temperature distillation this maximum will be increased to 12 gallons, and the resulting material from both a chemical and physical standpoint will be true gasoline, differing from gasoline obtained from petroleum only in its initial form, through the fact that it will contain a larger percentage of unsaturated hyrdocarbons. A large proportion of these unsaturated hydrocarbons, however, will be synthetically converted in the Ford Plant into their true gasoline form. and the cost of the gasoline produced by the new process is much less.

Universal Application

The importance of this development is not confined to the automotive industry, however. It is universal in application permitting the manufacture and production of the new motor fuel and equalizing the character of the products from the distillation of practically all carbonaceous deposits, so that the resulting coke will be of practically the same uniform quality, although the by-products will vary as to amounts of the several sub-divisions recoverable.

Coke Resembles Anthracite

The coke resulting from low temperature distillation is of a honey-comb-like character, and in the state in which it leaves the furnace is not suitable for shipment or use except in pulverized form as fuel for producing steam, when it can be so utilized without the necessity of transportation. This fuel, however, has all the properties of anthracite coal, and can be compressed so that sufficient density is obtained to permit shipment and storage.

In this compressing, or briquetting, process, it is necessary to use a "binder." In the Dominion of Canada there is available a vast quantity of what has been hitherto considered an absolutely waste product from the manufacture of pulp, know as "Sulphite Liquor," which, when concentrated, has proven an excellent binder. The low-temperature coke, when briquetted with Sulphite Liquor as a binder makes an entirely smokeless fuel, suitable for domestic purposes, and in the burning of which there will be absolutely no smoke or soot. A small percentage of pitch can also be used as a binder.

Chemistry of Coal

The chemistry of coal is very complex, and the number of chemical combinations recoverable from the products of coal distillation is practically limitless. There are certain commercial limitations, however, and only those elements which are most useful from an economic standpoint will be recovered in the Ford plant. Briefly, they consist of the following:

First—The coke, which will be burned in pulverized form under the power plant boilers.

Second—The surplus gas. of which about 4.000 cubic feet will be produced per ton of coal. This will be used in the forging and heat-treating operations required in the preparation of the high-grade steel for Ford cars.

Third—Sulphite of Ammonia, which is one of the cheapest and most valuable forms of fertilizer known.

Fourth—Creosote. a chemical in great demand as a timber preservative, especially for railroad ties.

Fifth—Gasoline and kerosene, of which a maximum of 12 gallons will be recovered per ton of coal and which contain all the properties of true gasoline and kerosene.

Sixth—Lubricating oils and grease,

which will not be taken from the oils remaining after the recovery of gasoline, kerosene and creosote at this time, but which may be utilized later for burning as ordinary fuel oil.

Value of Initiative

The value of the Ford Company's initative in its development to the Dominion of Canada is more thoroughly appreciated when it is considered that Canada has perhaps the greatest tonnage of lignite of any country in the world, large deposits of peat, and an appreciable amount of bituminous coal, but is without sufficient high grade coal to meet its domestic demands. Its supply of petroleum from which to derive gasoline and other petroleum products is limited. All of these factors result in the necessity for sending out of Canada a great amount of wealth to meet these necessities of modern existence.

Canada Has First Plant

Within the next few months, when the plant at Ford is completed, Canada will have in operation the first commercial realization of the research and development work which was carried on by V. Z. Caracristi, consulting engineer, and Emil Piron, chemical physicist for the last two years in New York, and which was verified semi-commercially in laboratories in Huntington, West Virginia. It would probably have taken these gentlemen and their backers several years longer to have secured the necessary financial assistance for the installation of a commercial plant, were it not for the fact that Henry Ford had previously expressed himself as vitally interested in the complete and economical commercial recovery of the by-products known to exist in coal before its destruction by burning.

The technical resources of the Ford Motor Company, Detroit, were placed at the disposal of the inventors. This assistance, headed by W. B. Mayo, has been of incalculable benefit in reducing the elements of uncertainty which naturally exist in any radical departure from accepted practice.

A similar plant, on a somewhat larger scale, is being installed at the River Rouge Plant of the Ford Motor Company, Detroit, but the Ford Motor Company of Canada is receiving preference, and its plant will be completed and in operation several months before the plant at River Rouge.

400 Tons of Coal Daily

The installation is for a plant to handle 400 tons of coal per day, but provisions have been made throughout for a plant to handle 2,400 tons of coal daily, so that additional units up to this capacity can be quickly installed, to keep pace with the plant's requirements.

Operations Continuous

All of the operations in Ford plants are continuous, not alone for production requirements, but in the maintenance of that accuracy which has been set up as a standard in Ford products. The low temperature distillation plant is also designed for continuous operation. The coal, lignite, or other material being distilled, is fed on a continuously travelling metal conveyor passing at the rate of approximately 25 ft. per minute through a sealed, heated chamber. The coal is stationary in relation to its carrier, and, being subjected to a "frying" action on a very hot plate, rapidly gives up its by-products in the form of gas. This gas is continuously taken off the furnace, its heavier portions condensed into a petroleum-like substance, its ammonia recovered through a continuous scrubbing operation with water, and the gasoline remaining in volatile form being brought into intimate contact with an absorbing oil which strips the gas of its burden of gasoline. This absorbing oil is continuously subjected to distillation for the purpose of recovering the gasoline, the gas going from this point directly to gas holders and point of ultimate consumption. The petroleum-like oil derived from the initial condensation of the gases is stored in wells, from which it is drawn and continuously distilled for the recovery of gasoline, kerosene and creosote fractions. The remaining oil is pumped to tanks and hence to point of ultimate consumption as oil fuel.

Crushed Coke Burned Like Gas

The coal, in raw state, is received by water or rail and stored in the river front coal storage plant, where facilities have been provided for the storage of 100,000 tons of coal. The coal is delivered, as required, by mechanical means, to a hopper from which it is fed into crushing mills which feed it upon a belt conveyor passing through a large reinforced concrete tunnel, and it is delivered by elevators and conveyors to steel storage bins of 100 tons capacity each. From these it is fed in a continuous stream one-half inch thick and eighteen feet wide to the primary distillation conveyor, and after passing longitudinally through the heating zone in the distilling oven, is dropped on a return conveyor which brings it back under the oven to a point directly under the feeders on the coal bin. After its passage through the oven the material has been changed from coal to low-temperature coke, and this coke, in lump form, passes through a screw type, water jacketed conveyor, and is again crushed to three-eighth inch size and under and elevated 100 feet to the level of the bunkers in the power plant.

It is fed to these bunkers through a dust tight screw conveyor, and is fed from them, by gravity, to pulverizing mills which reduce it to the consistency of flour. It is again elevated by an air current, integral with the pulverizing mill, to the height of the bunkers in which it is stored preparatory to firing under the power house boilers. From these bunkers the "Lopulco" pulverized coal feeders deliver it, as required, in the form of a dust-cloud, to the boilers where it is burned in suspension, like gas or fuel oil. The products of this combustion, passing through the boilers furnish the necessary heat for the production of the steam required in the power plant.

The coal, crushed coke, and pulverized coal are stored in large bins so as to provide against any temporary fluctuations in production, and this insures a continuous fuel supply for the boilers, which must operate without interruption.

Power Notes

The Residential Development Co., Montreal, have received a permit to build a power house on Simpson St., to cost in the vicinity of $11,000.

The City Council, Cooksville, Ont., is planning the installation of a power distribution and electric lighting system. The estimated cost is $30,000.

The Patterson Electric Co., 615 Yonge street, Toronto, have been awarded the electric contract for the new $20,000 school building at Cooksville, Ont.

The People's Electric Co., 656 Dundas St., London, Ont., have the electric contract for the new $50,000 registry office on King street for the city of London.

A. B. Carscallen & Co., Tamworth, Ont., are in the market for a belt-driven d.c., 125-volt generator, switchboard with equipment, one water-wheel, shafts, etc.

Daniel Reid Logan, Hamilton, Ont., manager of the B. F. Anderson Electric Supplies, died suddenly at his summer home at Burlington Beach, Ont., on July 15.

The City Council, Walkerton, Ont., plans to build a stand pipe and pump house, install gasoline-operated pumps and repair reservoir. Estimated cost $35 000.

Stan Lewis, 63 Metcalfe street, Ottawa, has been awarded the contract for the electric work in connection with the $150,000 office building on Sparks street, being built by the Sparks Estate.

Bernard H. Prack Hamilton, has been awarded the contract as architectural engineer for the new sub-station of the Hydro Electric Power Commission to be erected on Ottawa street, Hamilton. The approximate cost of this work is $45,000, and work will be started immediately.

Sir Wm. Arrol, Limited, St. Catharines, Ont., have been awarded the contract for the construction of the dam and power house for the power development of the Hollinger Consolidated Gold Mines at Island Portage on the Abitibi River. The plans call for the installation of equipment with a productive capacity of 25,000 h.p.

"A Good Time Had By All" At U.C.C.E. Picnic

By N. C. SHATFORD

Members of Canada Council No. 27 Enjoy Frolic at Ward's Island, July 21—A. M. Auchterlonie Again Victor in Keenly Contested Running Race

EVERYTHING in connection with the picnic of Canada Council No. 27, U. C. C. of E. on July 21, was true to form and with Old Sol working overtime and every one in good spirits it was only natural that the enjoyment of the day should be complete. Though it was a picnic, it must be understood that everyone worked hard—having a good time—young and mature, for there were no "old" ones there, taking part in the many items of sport scheduled by the committee in charge.

The usual races were run amid the usual excitement, the heat failing to dampen the ardor of those on frolic bent. Kiddies, arriving with their mothers, hopped around in an attempt to see everyone and everything at once, displaying such liveliness of spirit that it made one wonder "from whence this exuberance." The fair guests showed great satisfaction at being out of doors, knowing their children were quite safe playing around, glad to have a nice quiet chat—between races—with friends whom they see but occasionally.

As the engineers were in charge of the amusements they had little opportunity for "stalling," and everyone certainly deserves congratulations on the swing with which the whole afternoon went. It was a memory before one knew it, but a mighty pleasant one, put away side by side with the picnic on June 23 given by Ladies of Queen City Council.

The children of course enjoyed themselves thoroughly. Who ever heard of a kiddie not enjoying a picnic? It just seems to be the natural, accepted thing for them to go right ahead and do pretty much as they please, and they certainly made the most of their freedom from restraint.

In speaking to little Olivia Pope, her face was all smiles while the picnic and the coming exhibition were discussed, but when school was mentioned, there was a marked difference. "Yes, I'm having holidays now 'cause the school is closed, but I'll have to go back soon. You know, we go to school just twice as long as we can have holidays!" Such disgust, and so emphatic!

And little Alwyn Cudbird: "I don't know what we'd have done if it had rained to-day, but Daddy said it would be fine. Sure, I always come to these picnics."

Alwyn always goes to the picnics, he wouldn't miss one for anything!

The main excitement was the baseball game. The score was a bit uneven, Captain Davies and his team defeating Captain Holmes and his worthies, twenty-four to seven. The losers deserve credit, however, for they did all in their power to make the score appear less of a "walk-over," and the winners deserve credit for they had to work hard for the runs they got.

Congratulations are certainly in order to the entertainment committee, comprised of Chairman A. M. Auchterlonie, J. Grimshaw and T. C McAree.

Special mention and expression of appreciation should be made to T. C. McAree, who donated the ice cream, W. Russell Sexton who donated the milk, and C. Holmes, worthy chief of the council, who donated the tea and sugar.

The following are the races, winners and prizes:—

1. Tots' Race—O. M. Pope, Isabel May, Alwyn Cudbird and Albert Derbyshire.
2. Girls' Race—1st, Hazel May, doll; 2nd, Elsie Jenkins, beads.
3. Boys' Race—1st, Ronald Derbyshire, baseball; 2nd, Fred Davis, baseball bat.
4. Girls' Race—1st, Agnes Stephen, beads; 2nd, Helen Westwood, linen handkerchiefs.
5. Boys' Race—1st, Alex. Auchterlonie, baseball bat; 2nd, Lawrence Stephen, baseball.
6. Single Ladies' Race—1st, Anna Talbot, powder box and puff; 2nd, Helen Sexton, box stationery.
7. Single Men's Race—1st, John McBien, pr. silk socks; 2nd, Arthur Murphy, linen handkerchiefs.
8. Married Ladies' Race—1st, Mrs. Auchterlonie, rose bowl; 2nd, Mrs. Davies, aluminum pot.

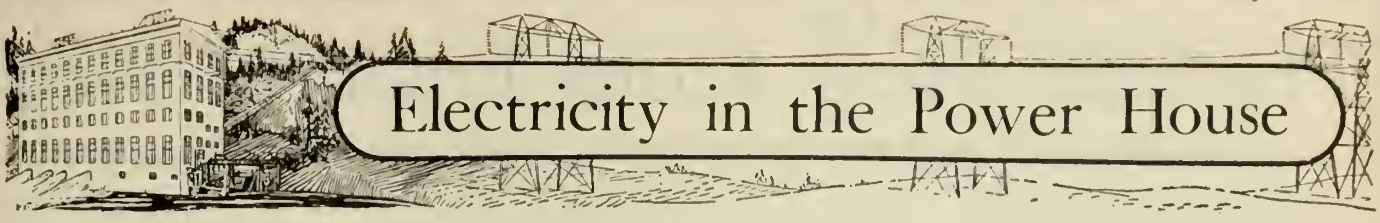
Engineers: Rear Row: Alex. Auchterlonie, T. Fisher, H. McConnell, K. McAree, F. Davies, J. Cudbird, W. Russell Sexton.



Electricity in the Power House

D. C. MOTOR SPEEDS

IT IS sometimes necessary to increase the speed of a direct current motor in order to compensate for excessive voltage drop in the supply or through a faulty choice of motor in the first place. In the case of small motors this increase of speed is often effected by shifting the brushes back. The variation thus effected is limited by the increase in sparking at the brushes.

A still further increase in speed can be brought about by putting a series winding on the fields. This also brings about sparking and has the further disadvantage of unduly heating the field coils.

Within limits, however, both of these methods can be used with success. A particular case was noticed in which both had been adopted and overdone, with the following curious result. On starting the motor up, unloaded, it started to rotate in a certain direction and nothing unusual was noticed on the first three notches of the starter. On the fourth notch, however, the armature stopped and commenced to rotate in the opposite direction. This continued as the starter handle was advanced and excessive sparking resulted. The machine tended to race away. Matters were put right by bringing the brushes into a more suitable position.

A moment's reflection will show that the cause of this was the demagnetizing effect of the series turns, together with the similar effect produced by the setting of the brushes. As the starter handle was moved, resistance was cut into the shunt field which, being weakened by the series turns, was overcome by the armature reaction.

It was impossible to start the motor under load as the field was too weak to give the necessary starting torque.

In modern design, a ratio of field ampere turns to armature ampere turns of 1.1 is often used. so that stability really depends on the 10 per cent. excess. If unauthorized persons add differential series windings this 10 per cent. is not a large margin to work on.

FRACTURED PISTONS

A certain small generating plant of about 70 kw. total capacity supplied a small town for general lighting purposes. The plant consisted of two d.c. generators driven by two gas engines. During an overhaul by an incompetent workman, the gudgeon pin on one of these engines had been "forced" back. As no apparent damage had been done, the engine was put into service, presumably none the worse for the rough treatment it had received. Trouble was first noticed a few nights later during peak load, when the engine became abnormally hot. The effect was progressive, and despite the greatest efforts of the station staff in increasing the circulating water supply and in an extravagant use of lubricant, the trouble got worse and finally the engine stopped.

At once the piston was withdrawn and examined. Both the piston and the cylinder were badly scored, and on closer scrutiny fine cracks were noticed radiating from the gudgeon pin. These were obviously due to the expansion of the pin under heat.

As it was impossible to get a new piston at short notice, a temporary repair was necessary. The pin was removed with some difficulty and reduced with emery cloth until it was a comfortable fit. The piston and cylinder were carefully polished with an oil stone and the cracked piston replaced. The engine then ran well for some months without giving any further trouble.

INDUCTION MOTORS

What is the difference between a squirrel cage and a wound rotor induction motor? Which is the better type for loads with a high starting torque?—John Davis, Toronto.

Answer—The rotor of the squirrel cage motor consists of a laminated core, in the periphery of which are imbedded heavy conductors, short circuited to one another by being connected to conducting end rings. In the wound rotors the conductors in the slots are in the form of coils, the ends of which are connected to slip rings. Brushes bearing on these rings make it possible to add external resistance to the rotor and by short circuiting the rings it is possible to get in effect the squirrel cage motor.

The induction motor depends for its torque on the slip, that is difference in speed of the rotating magnetic field and the rotor, the greater the slip the more current flowing in the conductors in the rotor, hence the greater the torque exerted.

The effect of increasing the rotor resistance is to increase the slip necessary to exert a certain torque. In this way the addition of external resistance in the induction motor gives a greater torque.

As the motor speeds up the resistance can be gradually cut out and the rings short circuited.

For heavy starting torque the wound rotor with external resistance is better than the squirrel cage induction motor.

Miscellaneous

The Canadian Mead-Morrison Co., Ltd., Montreal, Que., has been purchasing a considerable quantity of new equipment and machinery for its plate mill, including the latest type of rolls and gate shears and electric welding machines.

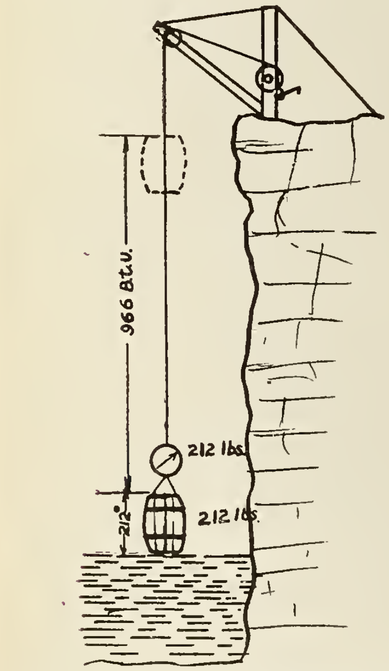
The Westco Manufacturing Co., recently organized in Toronto, with head office at 220 King St., W., has taken over the rights and organization of the Westco Pumps, Ltd., and will continue to manufacture pumps, water systems, etc.

Practical Ideas From Practical Men

SENSIBLE AND LATENT HEATS

Your recent article in Power House on the Benson Super Pressure Plant has made the question of sensible and latent heat a much discussed subject around our plant. In trying to make the matter plain I used the illustration shown in the accompanying sketch.

Let the suspended weight of the water in the barrel represent temperature, the spring scale in the lifting line the thermometer, and the power applied to the windlass above, heat applied. Then when the barrel is submerged the scale (thermometer) shows no weight (Temperature) but as the power (heat) is applied and the barrel is being raised out of the water, the scale (thermometer) registers a constant rise in pounds (degrees) until the whole weight (heat) of the water is indicated as 212 pounds (212 deg. F).



The barrel is now just clear of the water level and with a further application of power there is no further increase in weight and the scale cannot register the energy which is being stored in it, due to its elevation, just as the thermometer does not register any further application of heat beyond the boiling point.

The latent power in the barrel of water and the latent heat in the steam are both present in a changed condition, i.e., one case from a low elevation to a higher and in the other case from a liquid to a vapor.

If we let 966 feet of elevation in the case of the barrel of water represent the 966 B.t.u. of latent heat in each pound of steam at atmospheric pressure we will easily see the relation of latent to sensible heat.

The lowering of the barrel will return to the crank on the windlass, friction neglected, all the power which the water stored up when elevated just as the process of converting the steam to water will give up to the condensing water all the latent heat it held stored up in the vapor state.—R. MANLY ORR, 1551 Granville St., Vancouver, B. C.

AMMONIA LEAKS

While larger refrigerating plants are provided with safety helmets for use in case of serious ammonia leaks, small plants are seldom so equipped. For this reason the recital of what I did in one plant may assist some engineer on a like occasion.

In a refrigerating plant where gas-engine-driven compressors of 80 ton capacity were installed, a slug of liquid ammonia caused a gasket to blow out on the crank-end head of the compressor. The engine room was soon full of fumes, the other machines were still running and no helmets were in the plant. The engineer called up and I was sent to the plant to see what could be done.

When I got there it was impossible to enter it on account of the fumes which filled not only the building, but the street outside. I got all the information possible from the engineer as to the location of the valves and the particular machine that was leaking, there being three machines in the plant.

I then secured a quart of vinegar and after saturating heavy towels with it, wrapped these towels over my mouth and nose. After three attempts I managed to get the suction valve closed, and followed this up by closing the discharge valve. The engines were then shut down, and since there was a brisk wind blowing, the plant was soon cleared of ammonia fumes.

We then removed the piston and cylinder head and replaced the rubber gasket, which had sprung a leak, by one which we cut from a sheet of lead. We then reassembled the compressor and repacked the piston-rod stuffing box and started up after a shutdown of but seven hours and with only a small loss of ammonia.

FAULTY LUBRICATION

In vertical steam engines used around the power house for such purposes as driving fans, stokers, etc., it is customary to use a self-oiling type, in which the base of the engine acts as an oil reservoir. The oil is then pumped continuously to all parts of the engine by means of a small pump.

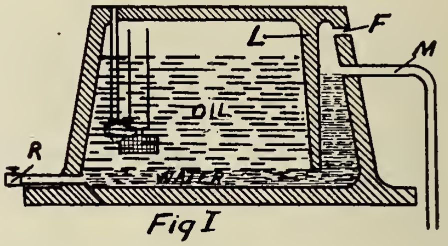


Fig I

Water leaking from the stuffing box finds its way to the oil sump and being heavier than oil collects in the bottom. If suitable means are not provided for removing this water continuously, it is only a matter of time until it will rise to the suction level of the oil pump, then the oil and water will sludge.

To prevent trouble from this source most engine bases are made as shown in Fig. 1, the lug extending to about one inch from the bottom of the base. A vent should be bored at F otherwise the drip pipe M will act as a siphon and empty the oil sump.

In one power plant, a stoker engine of the self oiling type, with an oil sump located in the base, gave trouble from the start unless the engineer drained the water at frequent intervals through the drain cock R. On examination it was found that the suction end of the oil pump extended to within ½ inch of the bottom of the oil sump, and that there was no method provided for continuous draining of the water.

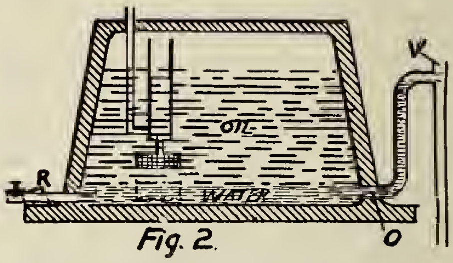

Fig. 2.

The trouble was overcome by the pipe arrangement shown in Fig. 2. A hole was drilled and tapped for ⅜ pipe, with the top about 1 inch above the bottom of the oil sump. An air vent was provided at V by using a T instead of an elbow. The suction strainer was also raised about an inch and all trouble with the lubrication of the engine ceased. Geo. Walsh, Winnipeg, Man.

The Goldie & McCulloch Co., Galt, Ont., held their annual picnic in Victoria Park on Saturday afternoon, July 21. About 400 were present.

Every-day Problems With Answers

Queries are invited on the every-day problems of all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped to solve a problem and a pleasure for us to pass on the data.

OIL ENGINES

What is the difference between the Diesel and the semi-Diesel engine, and which type is used in the large units? Is there any distinction between fuel oil and crude oil? —A. L. T.—Sarnia.

Answer.—In the true Diesel engine pure air only is drawn into the cylinder on the suction stroke, then compressed to a pressure of 500 to 600 lb. per sq. in., raising the temperature of the air at the end of the compression to such a degree that the oil sprayed in by the fuel valve is ignited at once, air pressure of about 1,000 lb. per sq. in. being used for atomization of the fuel. In the semi-Diesel the compression pressures are much lower, usually from 250 to 300 lbs. The temperature resulting from these low pressures is not sufficient to cause ignition of the fuel in a cold engine, additional heat, therefore, must be supplied by some other means, usually by a hot bulb or uncooled part in the clearance space, into which the fuel is injected at the end of compression.

The temperature in the hot bulb is always sufficiently high to cause ignition of the injected oil. In the semi-Diesel air pressures of 500 to 600 lb. per sq. in. are sufficient to secure proper atomization of the oil.

The main differences, therefore, between the two types are, lower compression pressures and the use of an uncooled part of the combustion chamber of the semi-Diesel, making preliminary heating necessary for starting, whereas the Diesel can start cold.

The Diesel engine is favored for the large power units because of its higher efficiency and better performance with fluctuating loads; the semi-Diesel is used in smaller units bceause of its lower costs, and the slightly lower efficiency is then not so important a factor.

Crude oil is the oil as it comes from the well, containing gasoline, kerosene, lubricating oils, etc. It is very seldom used in oil engines on account of the danger from the light fractions and because it contains gasoline and kerosene, making it too costly. Fuel oil is the residue after the light fractions have been removed. This is the fuel commonly used in the oil engine on account of its lower cost and the fact that it is not dangerous to transport or store.

BOILER COMPOUND

We use the following as a boiler compound: 60 lbs. sal soda, 12 lbs. caustic soda, 8 lbs. japonica, 2 lbs. magnesium dioxide, 2 lbs. Irish moss.

From what are the above ingredients obtained and what is their chemical symbol? What is the effect of the compound and each of the ingredients upon water in Toronto at a temperature corresponding to 120-lb. gauge?

—E. Golightly, Toronto.

Answer.—Sal soda or sodium carbonate (Na_2CO_3) is made from salt and limestone. Caustic soda or sodium hydroxide (NaOH) is strongly alkaline and is made from sodium chloride (common salt) NaCl. Irish moss and japonica are of vegetable origin. Magnesium dioxide does not exist commercially. In all probability you mean manganese dioxide (MnO_2) which is found in a black rock-like material. The sodium carbonate acts on the calcium and magnesium salts in the water, changing them to insoluble carbonates, which precipitate out.

The caustic soda precipitates any iron or aluminum compounds as hydroxides.

Manganese dioxide is an oxidizing agent and tends to hasten the precipitation of the calcium and other salts in the water. The finely-divided precipitate carries down any sediment or colloidal material suspended in the water.

The functions of the Irish moss and the japonica are not clearly understood, but they are believed to give a colloidal solution which acts as a protective colloid preventing the precipitated materials from compacting to a hard dense scale on the boiler tubes and sheets.

The compound as a whole, therefore, precipitates the salts contained in the water as insoluble compounds and these help to carry down any sediment or finely-divided materials in the water. The temperature of the water has little effect on the final reactions but as in most chemical changes the higher the temperature the faster the reaction.

LOOSE PISTON RODS

If the fastenings of the piston rod of an engine to the crosshead become loose, how can the proper position of the rod be found?

Ans.:—Loosening of the piston rod in the crosshead would be revealed by a hammering noise at the beginning of each stroke, and sufficient withdrawal of the rod out of the crosshead would cause the piston to pound in the head end of the cylinder. The length of the connecting rod and connection of the piston rod with the crosshead should be such that there will be equal piston clearance in opposite ends of the cylinder.

For the purpose of making the adjustments, remove the cylinder head, place the engine on a center and make a mark on the crosshead that corresponds with a mark made on the guide; and turning the engine over to the other center, make another mark on the guide to correspond with mark previously made on the crosshead.

The distance between the marks on the guides will represent the length of the stroke.

Next disconnect the connecting rod, replace the cylinder head and move the crosshead to bring the piston hard against first one end and then the other end of the cylinder, each time make a mark on the guide to correspond with the mark on the crosshead. The distance the crosshead has thus been placed beyond the marks previously made on the guide will be the piston clearance at corresponding ends of the stroke and should be the same for each end of the stroke.

When the piston rod is screwed into the crosshead, considerable adjustment for equalization of the piston clearance for opposite ends of the stroke can be obtained by screwing the rod in or out of the crosshead, but the rod should be set with a length of the threaded end in the crosshead of not less than its diameter, plus two or three additional screw threads. In case equalization of the piston clearance by screwing the rod out of the crosshead could not be obtained without shorter length of the screwed end of the piston rod, or the rod is a taper fit in the crosshead, then equalization of the piston clearance must be made by proper shimming of the connecting rod.

DRAFT LOSSES

In a water-tube boiler if the draft over the fire is shown by the gage to be 0.1 in., and the draft in the uptake is 0.4 in., does the difference, or 0.4—0.1=0.3 in., show the draft loss through the boiler? If not, how can the resistance be found?

Ans.:—If the draft over the fire is taken near the tubes at a point where the draft gage gives a constant reading, the difference between that indication and the draft in the uptake should be fairly representative of draft loss through the boiler. The more accurate method of obtaining the draft over the fire is to protect the draft-gage connection from currents and eddies of the gases.

CYLINDER CLEARANCE

How is measurement made of the cylinder clearance volume of a steam engine?

Ans.:—The cylinder clearance volume in each end of the cylinder is most readily determined from the volume of water that can be contained by the clearance space when filled from the piston, when at the end of the stroke, back to the valve seats. An opening needs to be provided at the top of the cylinder at each end for introducing the measuring water; or the water may be introduced through the indicator connections, using a standpipe of sufficient height for completely flooding the clearance space, with suitable provision for escape of air from the cylinder during the process of filling.

Place the engine on dead center with the piston in the head end of the cylinder, and after removing the valves, cover each valve seat with a rubber gasket, held down tight by a block of wood wedged or bolted in place. Pack candlewicking around the piston to prevent leakage of water past the piston. For this purpose the cylinder head must be removed and again replaced.

Provide two vessels, each filled with clean water and take the weight of each. Then fill the clearance space of the head end from one vessel and make a note of the time required. As soon as the space is filled, the first vessel is to be set to one side and subsequently determining the weight of the water thus used, and the clearance space is to be kept filled against leakage for five minutes by adding water from the second vessel. The vessels are again weighed to determine the weight of water used from each.

The average rate of leakage while filling the clearance space from the first vessel may be assumed to be one-half of the rate during the filling against leakage from the second vessel. If $W =$ weight in pounds of water required to fill the clearance space from the first vessel; t minutes $=$ the time required; and $w =$ the weight of water in pounds necessary to keep the clearance space filled against leakage for one minute, then the leakage during the filling is approximately $(w \times t) \div 2$, and the clearance space will contain $W - [(w \times t) \div 2]$ lb. of water. This multiplied by 27.7 gives the space in cubic inches.

ENGINE POUNDING

Recently, I took charge of a steam plant having a 125-hp. engine. Several engineers had been tried, but none of them had been able to locate the cause of a heavy pound.

I made a general survey of the engine and then took indicator diagrams, but the valves were found to be properly adjusted. It was decided that the engine might be out of line. It was taken down and then lined up. In reassembling the main bearings, crank and crosshead brasses were properly adjusted and the piston examined to see that it was not loose on the rod; in fact, the engine was put in good shape. When it was started, the pound was still present.

I shut down and the engine stopped on the center. I took hold of the flywheel to turn it off and noticed a slight lost motion. It then struck me that the flywheel was loose on the engine shaft.

An examination showed that the key had worked out slightly, which allowed the flywheel to be loose enough to cause the pound when it travelled over certain quarters. I put in a new key and drove it in snug, and there has been no trouble since.

Construction

Shavers Laundry Co., Ltd., 95 Canning St., Montreal, are in the market for one 60 h.p. steam boiler.

The Garden City Paper Co. plan to build a paper mill and are in the market for electric motors, etc. Estimated cost to be $400,000.

The Niagara Falls Arena, Ltd., are planning to build a new arena, 258 x 270 ft., on Victoria Avenue. Estimated cost $55,000. The owner is in the market for 30-ton ice manufacturing units.

The Sisters of Quebec Hospital, 11 Palace Hill, Quebec, are having plans prepared for the construction of a three-storey hospital including steam heating system. Estimated cost $600,000. Stevens & Lee, 62 Charles St., Toronto, are the architects.

The Canadian Comstock Co., Ltd., 10 Cathcart Street, Montreal, have been awarded the contract for the electrical work in the asbestos mill being built by the Asbestos Corporation, Canada Cement Building, Montreal. Estimated cost of the building $500,000.

The Hydro-Electric Power Commission, University Ave., Toronto, are having plans prepared for the construction of an addition to the transformer station on Davenport Road. Estimated cost $150,000. Purchase will be made of transformers, switches and electrical equipment.

The Ottawa & Hull Power Co., Hull, Quebec, have had plans prepared and will soon call for tenders for the construction of a dam, 400 ft. long, across the north branch of the Ottawa River near Bryson, Que., to include 75 x 450 ft. canal, headgates, etc., power house, 50-mile transmission line to Ottawa and substation at Ottawa. Estimated cost $1,000,000. They are in the market for three vertical shaft turbine units with generators, exciters, etc., 22,500 h.p., also electrical equipment, electrically-operated cranes, etc., for power house at Bryson, and step-down transformers, etc., for distribution of power, 66,000 volts, for substation at Ottawa.

The Liquid Air Co., with headquarters at Paris, France, have taken up with the Board of Trade, Sault Ste. Marie Ontario, the advisability of the establishment at the Sault of a half-million dollar plant for the manufacture of oxygen and acetylene gas. The company have a few plants in Canada, and if a sufficient market can be secured for their output are desirous of locating at Sault Ste. Marie.

The British Columbia Electric Railway are rushing work on the new million dollar dam at Stave Falls to increase the storage of Stave Lake, which will be ready by early fall. This is a sluice dam, 60 ft. in height, and will increase the storage of Stave Lake from 168,000 acre-ft. to 465,000 acre-ft. Anticipating the additional water supply, in 1922 a fourth unit of 9,000 kvs. was installed in the Stave Falls plant, bringing the capacity up to 36,000 kvs. Owing to the higher elevation of the lake due to this dam, the Blind Slough dam immediately above the plant is being raised 22 ft. If permission can be obtained by the company from the provincial government, they propose to divert the waters of Lake Alouette, lying above Stave Lake, through a 10,000 h.p. plant under a head 140 ft. As the demand for power increases following this development, a fifth unit of 25,000 h.p. capacity will be installed at the Stave Falls plant, and later a third plant will be built near the junction of the outlet to Stave Lake and Fraser River which will develop 80,000 h.p.

Personals

Frank Rutherford, Department of Technical Education, Parliament Buildings, Toronto, has been appointed honorary chairman of the Educational Committee of the Canadian Association of Stationary Engineers, and M. Barry Watson, Director of Engineering at the Central Technical School, Toronto, and Arthur Murphy, editor of "Power House," University Avenue, Toronto, have been appointed members of the Educational Committee.

W. Russell Sexton, of the W. R. Sexton Boiler Setting Co., 127 D'Arcy Avenue, Toronto, was responsible for the finding of the Studebaker Six car used by the men who robbed messengers of the Bank of Nova Scotia and the Sterling Bank in Toronto on July 24. Mr. Sexton, while walking with two friends on July 29, located the car in an isolated barn on the Dunlop Farm about ten miles northeast of the city limits. The finding of this car is the first definite clue uncovered in the robbery.

Progress in New Power Equipment

AMONG recent improvements in Canadian refrigeration plants is a new unit installed at the Chateau Laurier Hotel, Ottawa, Ont.

During the past few years many steam driven ammonia compressors have been discarded in favor of synchronous motor driven units and this installation is a good example of this practice.

The machine, which was built at the Canadian Ingersoll-Rand Co's Sherbrooke plant, is an 11 and 7-¾x12 inches Class PRE-2A direct connected motor driven, horizontal, duplex, double-acting, two-stage unit, without intercooler and has hand-operated clearance control pockets for regulating the capacity in three steps viz, full, three-quarter, or one-half load.

The motor is a Canadian Westinghouse 155 H. P. 237 R. P. M. unity power factor, 80 degree, two phase, 60 cycle, 2,200 volt, engine type, direct-connected motor with belted type exciter.

The compressor operates at 257 R. P. M. and is rated at 68 tons when operating with 15 lbs. back pressure and 185 lbs. head or discharge pressure.

The load assumed by this compressor was formerly handled by two old style steam-driven machines and comes principally from a brine cooler which serves the Chateau and the remainder from an ice making tank and an ice storage room.

The compressor is located in an extension of the central power plant. Cooling in the Chateau is accomplished by brine circulation. the brine being cooled in a double tube brine cooler situated near the compressor, ice tank, etc., at the power plant. The brine cooler is of course installed in an enclosed insulated compartment.

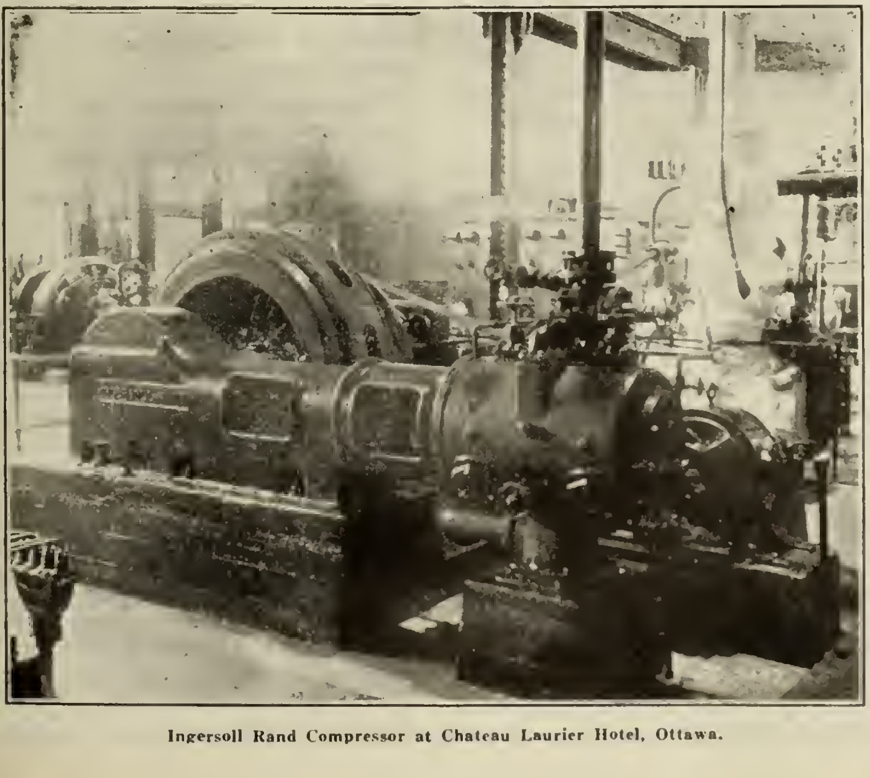
The reasons for installing this compressor were as follows: Electric power is generally so cheap as compared with steam that as is usually the case, conversion to electric drive was warranted even on the basis of installing new equipment.

A little more capacity was needed for handling the extreme peak load on hot days in summer and still more capacity was desired to take care of contemplated increases in ice-making load.

Synchronous motor drive was desired on account of its numerous advantages and a high speed direct-connected unit, permitting large output for floor space occupied, was practically imperative on account of the limitations in this respect.

It was also desired to install a unit having capacity considerably in excess of that demanded by existing requirements and yet be able to run it at partial loads to meet present needs. This condition was met by the hand-operated clearance control pockets. These act on a principle similar to the Ingersoll-Rand patented Automatic Clearance Control for Air Compressors and permit efficient regulation, without disturbing the mechanical, balance of the machine, at full three-quarter and half-load, with practically corresponding reductions in power consumption.

In addition to electrical driven units the company also makes a complete line of straight line steam and belt driven machines and belt and steam duplex units, for large or small plants



Ingersoll Rand Compressor at Chateau Laurier Hotel, Ottawa.

CLEAN AIR

An important but frequently overlooked factor in modern conservation, both of health, machinery and power plant equipment is clean air.

Chemical analysis shows that air is charged with fine particles of dust resultant from the disintegration and decomposition of every conceivable substance exposed to wear and tear, combined with that dirt which is the accompaniment of modern industry.

Thousands of tons of stone, coal, cinders, ashes, sulphuric acid, sulphuretted hydrogen, carbon bisulphide, ammonia, chlorides, sulphates, salts and fetid matter are suspended in the air or allowed to settle on the floors and walls of structures and street pavements, and clean air is therefore a commercial economy, an important factor in lowered depreciation of equipment, and in improved product with lowered costs.

Depreciates Machinery

It is obvious that fine stone, sand, carbon, soot, etc., which is suspended in the air in large quantities, must have a seriously deleterious effect upon machines and upon many products.

Certainly coarse "dust" is most injurious to moving machinery of all kinds. With compressors, gas engines and similar machinery, the "dust" combines with the lubricating oil or water and is deposited upon the cylinders, pistons and other parts where it serves as a very effective cutting compound. Thus it causes friction which results in excessive wear, rapidly lowers efficiency and causes frequent and expensive repairs.

In the case of electrical machinery, such as generators and air-blast transformers, dirt particles are sucked in slowly but continuously and clog the narrow air passages through the iron cores and are deposited upon the windings.

This partial stoppage of the air ducts, and often the ducts are completely filled by this dirt, reduces the flow of the air and increases the temperature of the machine. The accumulation on the coils is a poor heat conductor and is another cause for an increase in the temperature of the machine.

An increase in machine temperature must result in a reduction of the capacity of the machine, and such temperature rise may attain dangerous proportions. This can only be minimized by the more frequent cleaning of the machine which may result in taking the machine out of service at an inopportune time and must result in increased operating costs.

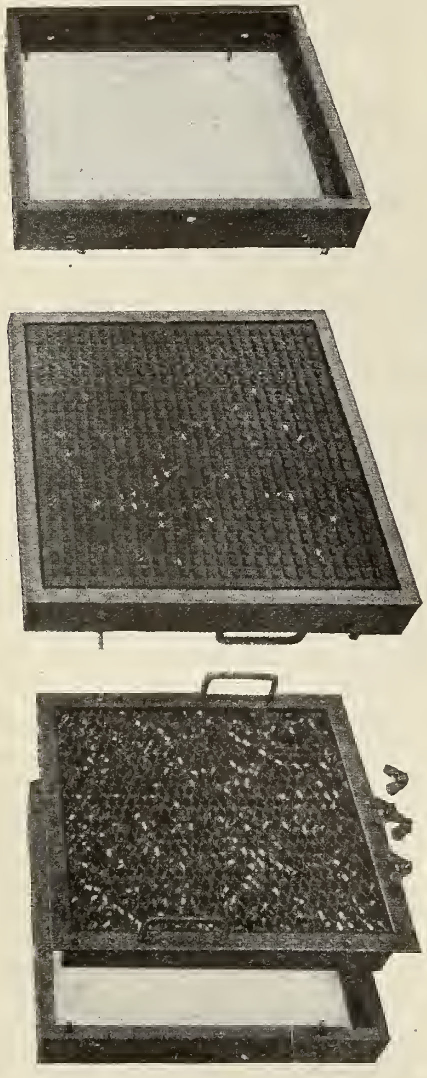
Dust Highly Injurious

It is obvious that the elimination of such "dust" from atmospheric air must bring increased efficiency to machinery, prolong its life and save money for the plant to a marked degree.

It is only during the last decade that this subject has been studied by the engineer and air-filters have become a scientifically designed product.

There are three main types or principles involved in the air-filters marketed to-day. The washer type, where the air is forced through a curtain of pumped water; the filter using a cloth or similar close-meshed screen; and the type using small hollow cylinders placed in a shallow rectangular box or "filter cell."

The method of filtration is based upon the principle of passing the atmospheric air through layers of small, irregularly placed metal cylinders, (filter bodies) which are coated with a non-drying, non-freezing viscose fluid especially developed for the purpose, called Viscosine.



The frame, cell, and complete air filter unit.

Filter Bodies Coated

Dust laden air encountering these layers of "filter bodies" is split into innumerable fine streams which are constantly forced to change their direction and thus the air winds its way through, depositing much of its "dust" content in the many corners and pockets. The balance of the "dust" is arrested by the coating upon the "filter bodies."

This type of air-filter is built on the "unit" principle.

These filter units comprise two elements, namely a steel frame and a filter cell fitting into the frame, with air-tight joints. The cells are 20" square with fronts and backs of specially perforated metal and are filled with "filter bodies." Each cell has two handles conveniently arranged so that one man can remove it easily for its periodical cleaning and recharging operations.

The frames are provided with "hooks" corresponding to eyes in the flanges of the cells, thus providing a simple effective means for holding the cells in place.

The filter units may be arranged in one or more planes, or in the form of boxes, etc., all depending upon local conditions and space available. Any local space may be utilized for the simple installation of this filter. They may be installed upon the roof or in the outside wall of the building as well as inside, without any decrease in efficiency.

For any given installation, the filter units are set side by side, or above each other; the frames are bolted securely together, thus forming a skeleton framework into which the filter cells are placed.

This type of air-filter is manufactured by the Midwest Steel & Supply Company Inc., of New York. This company is extending its activities to Canada and application has been made for a Canadian charter and a Canadian Company is being formed.

Willis D. Bishop of Bishop Sales Corporation, Montreal, is manager of the Canadian Company.

The field will be covered by district managers in the large centers in order to handle properly the needs of local industries.

Announcements

The Canadian Oil Co., Petrolia, Ont., held its annual picnic at Tashmoo Park on July 26, 1923. More than 500 people from Petrolia attended, and a number of visitors from Oil Springs and Oil City.

Goldie & McCulloch Co., Galt, Ontario, have shipped to St. John's Drydock & Shipbuilding Co., St. John, N. B., three Rees-Roturbo pumps, 48 x 42 in. volute type. These pumps are of a capacity to empty a drydock 1,200 ft. long by 120 ft. wide, containing fifty million gallons of water, in four hours.

The installation of new equipment, including boilers, in the municipal electric light plant at Kenora, Ont., is being considered.

The Canadian Fairbanks-Morse Co. are supplying motors and pumps for a waterworks system, valued at $8,000, in Duncan, B. C.

The Southern Canada Power Co. will probably call for tenders in September for the power development of Hemmings Falls, Quebec.

The Hydro Electric Commission of Ontario is contemplating the installation of three 100 kvs. transformers at the station at Acton, Ont.

The Hydro Electric Power Commission of Ontario is planning to build an addition to the transformer station on Davenport St., to cost about $150,000.

The Lower St. Lawrence Power Co. has been granted permission to erect a transmission line from Rimouski to Reviere Metis, about 22 miles distance.

The Hydro Electric Power Commission, Toronto, are considering the erection of a transmission line from Tilsonburg to Courtland, Ont., approximate cost $40,000.

George Crawford has been appointed electrical instructor at the Ottawa Technical School, his duties to commence in September. He formerly held a similar position in the Hamilton, Ont., tehcnical school.

M. C. Smith, superintendent of Light, Power and Railway department of the Nova Scotia Tramways & Power Co., Halifax, N. S., has been appointed manager of the Cape Breton Electric Co., Sydney, N. S., succeeding C. C. Curtis.

William Kennedy and Sons, 232 St. James St., Montreal, have been engaged by the Ottawa and Hull Power Co., to prepare plans for a power plant and dam to be erected at Cat Calumet Island Falls on the Ottawa River, near Bryson, Quebec.

The Sinclair Construction Co., Toronto, Ont., have been awarded the contract for the building of the new power house at Campbellford, Ont., by the Hydro Electric Power Commission of Ontario. The tender includes the erection of the power house and tail race, and is for $250,000.

Robert Taschereau, K.C., Montreal, and Hon. Honore Mercier, Minister of Lands and Forests, the former representing the Des Quinze Power Co. of Ontario, and the latter the Government, have signed the contract for the sixty-year lease of the third group of the Des Quinze River.

Dan M. Logan, identified with the Canadian General Electric, Toronto, for twenty years, latterly as sales manager of the lamp department, died in Hamilton on July 15, 1923. On May 1st, Mr. Logan severed his connection with this company and became associated with B. F. Anderson, Hamilton, Ont., in a lamp jobbing business.

BUYING THE RIGHT COAL

(Continued from page 23)

tent of the coal which you are using. It is common to speak of an evaporation of 8 or 9 or 10 pounds of water per pound of coal as representing a relatively high efficiency. Such figures, however, mean nothing, unless the B.t.u. content of the coal is also given. For example, if coal contains 11,000 B.t.u. per pound, the equivalent evaporation of 8 pounds of water per pound of dry coal would represent 70.5 per cent. efficiency. However, if the coal contained 14.500 B.t.u. the evaporation of 8 pounds of water would represent only 53.5 per cent. efficiency.

Complete analyses of coal entering your plant should be made at frequent intervals. If you haven't a laboratory of your own put a barrel in the boiler room, have the fireman throw in a shovel from different parts of the car to be tested, then mix and quarter the contents of the barrel until you have a representative sample which you can forward to the nearest testing laboratory. In making a contract for the purchase of coal under specifications the following points should be taken into consideration:

(1) Amount and description.
(2) Time and condition of delivery.
(3) Adjustment in price for variations in B.t.u. content, moisture, and ash.
(4) Method of sampling.
(5) Designation of laboratory.
(6) Disposition of acceptable coal.

Proper selection of coal is at the very foundation of efficient power plant management. Time invested in the study of this question will pay rich dividends.

OIL ENGINE BEARINGS

(Continued from page 24)

much bearing wear and shaft bending can occur and still not require new bearings or readjustment? The allowable wear will vary in different sizes of engines. For engines over 200 H.P. the difference should not exceed 0.008 in. to 0.01 in. Smaller engines, having smaller shafts, can, of course, stand a greater variation, say up to 1-64 in. On the other hand thousands of semi-Diesel engines are running with bearings as much as 1-16 in. out of alignment. That such engines do not break their shaft speaks a lot for the high quality of the steel used.

The engineer who finds that the bearings are out of alignment is now up against the problem of realigning them. Many raise the low bearing by putting shims under the shell. The great objection to this is that one cannot be sure that the shim is supporting the shell, save at the bottom. The shell may break as a result.

High bearings should be scraped until they are as low as the worn ones. This is an easy job, and a scraper can be made of an old flat file. The edges are ground off square and will cut the babbitt without any trouble.

Coloring Rubs Off

After scraping the high bearing, all should be measured or "miked" to get them to agree. Upon being placed in the housing, lampblack, prussian blue, or red lead should be smeared lightly over the shaft. At all points where the shaft touches the babbitt the coloring will rub off on to the babbitt. By removing the shells again, these high spots may be scraped to bring the babbitt in contact with the entire journal. After the lower bearing shells are adjusted, the upper shell or cap must be replaced with running clearance.

Just how much clearance is necessary between the shaft and cap is a question. It is safe to make this 0.01 in. for shafts up to 6 in. in diameter and 0.007 in. for larger shafts. There is no reason for clearance at the top, save clearance for the oil film and to provide for the expansion of the shaft by reason of the working temperature.

Test Third Method

A third method of detecting low bearings (see Fig. 3) assumes that a low bearing will cause the width between the crank webs to change by the deflection of the shaft when the engine is turned so that this particular crank is at top centre and then at bottom centre. By measuring between the webs, by means of an inside micrometer, any change in the width may be detected at once.

If the crank to the right of this crank also shows a deflection, it is proof that the bearing between the two cranks is low. On the other hand, if the crank to the left shows a deflection while the one to the right does not then the left bearing is low.

This method is excellent, but the engineer must be careful in taking the measurements. It is necessary in most cases to remove the connecting-rods; but if the flywheel overhangs, removing the weight of the rods and pistons will cause the shaft to bend, thus giving incorrect measurements.

REDUCING VALVE ECONOMY

(Continued from page 30)

cent. efficiency at a certain pressure. A higher pressure of steam does no more work than the predetermined lower pressure, it simply wastes steam. If the conveyor works efficiently at 90 pounds pressure and your boiler pressure ranges from 160 to 180 pounds, the reducing valve, regardless of boiler pressure change, delivers steam to the jet at 90 pounds pressure.

The fifth reason for using reducing valves is that they do something that cannot be done properly by any other means. This is almost self-evident.

It is admitted that a globe or stop valve may be so manipulated as to reduce a pressure and control the flow of steam, but because both factors are changing, that is the high pressure is fluctuating and the low pressure will fluctuate answering a greater or lesser demand, it is necsesary that the stop valve have personal and continuous attention if proper control is to be secured. First, because the man who operates the globe valve will only respond to the fluctuations as they occur and he sees them recorded on a gauge; whereas, the reducing and regulating valve responds instantly to the changes, being controlled by them as they change, offsetting the one tendency or the other at the exact moment it occurs, so that the reducing and regulating valve is not only more efficient, as it prevents rather than corrects aberrations, but is profitable investment in that, being automatic, it saves labor.

Is a Money Saver

While often looked upon as an expense, the pressure reducing and regulating valve is in reality the means of saving a great deal of money. Here is a simple example. You undertake to generate steam as economically as possible; that is, at high pressure, say 250 pounds superheated 200 degrees. You set out to buy stokers and discover that the equipment is designed and manufactured to operate at 80 pounds pressure. But there is no necessity for buying specially designed equipment to withstand your high pressure, for the reducing valve steps in and turns the trick.

It reduces your 250 pounds superheat pressure to the 80 pounds pressure at which the stoker equipment will perform efficiently, saving you expensive apparatus for high pressure service. To carry the idea further, it is apparent that because of reducing valves the stoker manufacturers can make one class of equipment for standard pressures and produce them in quantity at a great saving in price.

Clogged With Debris

But I didn't finish my story. For it so happened after a space and a time Al Hassan sent for Mech-Anic and charged him with carelessness in the construction of his valve, for it had ceased to function. Upon inspection Mech-Anic found that it had become clogged with debris and filth. He ordered it cleaned and had a strainer woven of rushes placed before it to protect it and so reported to Al Hassan. But Al Hasson still found fault, saying, "We have ever had trouble with the valve since you made it."

Whereupon Al Hassan, being a just man, ordered him a thousand pieces of silver, a gift of horses, and corn more than he could carry away.

All of which is to say, that a regulator should be protected from damaging scale and grit by a strainer; that, being in reality a piece of automatic machinery functioning continuously, it should be given the care usually accorded machinery of that sort; that having moving parts it is eventually bound to wear; and that if given care, it really does for you automatically and dependably something that could not otherwise properly be done.

CLASSIFIED ADVERTISEMENTS

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads set in border, are at the card rates.

Every Engineer, Mechanic and Electrical Worker will welcome this new master set. It will answer your problems.

It will help you with your daily work.—A sure source of advancement and higher pay. Complete up-to-date information that is thoroughly and easily explained on every branch of modern engineering and electrical practice.

POSITIONS WANTED

FACTORY SUPERINTENDENT OR CHIEF Engineer is open for engagement. Have had wide experience in operating power plants and handling help in Canada. Apply Box 107, Power House.

REFRIGERATING AND MECHANICAL ENgineer with 10 years' operating record, also with experience in heating and lighting work, desires employment in Toronto. Apply Box 108, Power House.

POSITIONS VACANT

STATIONARY STEAM ENGINEER WANTED—familiar with water tube boilers and Turbo Blowers and Generators. Must be an all round competent man, capable of taking charge of plant of about 2,400 B.H.P. Must have first class certificate. State in first letter salary wanted, age, experience, and when you can report. Apply P. O. Box 720, Port Colborne, Ont.

WANTED — SALES ENGINEER—EXperienced in steam specialty lines. University graduated preferred. Write stating experience and salary. Apply Box 109, Power House.

FOR SALE

BURNHAM STEAM PRESSURE PUMP, 10 IN. x 1⅛-inch. x 12 in., nearly new, with Fisher governor attached. W. Ahearn, 538 McLaren St., Ottawa. When answering this advertisement please mention this paper. P.F.H.

INDUCTION MOTOR — 220 VOLTS — 1800 r.p.m. 15 h.p.; single phase; can be bought cheap; write for particulars. Box 104, Power House.

I. H.C. 12 H.P. GAS ENGINE FOR SALE—ALL in good running shape, with 33-inch clutch pulley; will be sold reasonable on easy terms. Apply W. Harrison & Son, R. R. No. 5, Guelph. When answering this advertisement, please mention this paper. P.F.H.

DO YOU Manufacture Industrial Equipment?

Are you a manufacturer of twist drills, hack saws, mechanics' tools, wire guards, bolts, rivets, paints—do you manufacture lines of any description that can be used in machine shops, metal-working plants, power plants or foundries? If you do the publications you see illustrated here (Canadian Machinery, Canadian Foundryman, and Power House) can build a bigger demand for your products.

This group of technical newspapers is read by the men who are prospective buyers of your lines. You can bring to the attention of these men the reason why they should demand your goods when purchasing from their dealers. You can effectively do this by placing a message in the paper which serves the field in which your products are sold.

CANADIAN MACHINERY AND MANUFACTURING NEWS is published weekly and covers the machinery, iron and steel and general metal-working industries of Canada.

POWER HOUSE is published twice a month; it serves steam, electrical, water and gas power plants, and the power houses of all general manufacturing plants.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS is published monthly; it serves the grey iron, steel and non-ferrous foundries.

These publications reach proprietors, managers, purchasing agents, foremen—the men who direct the purchasing of goods. A message to these men in any of the MacLean Technical Newspapers is certain to have a strong influence.

Write for complete Data.

The Unique Construction of the ANDERSON STEAM TRAP

enables you to place it anywhere there is condensation to handle. Absolutely prevents the escape of the live steam. Equipped with a removable strainer which prevents scale, packing, etc. from entering the valve

Positive-acting, with every part interchangeable, the Anderson Model "D" is the most effective Steam Trap because it automatically adjusts itself for any pressure within its capacity. Ask for our catalog giving full particulars.

THE V. D. ANDERSON CO.

1935 West 96th St., Cleveland, Ohio

De Laval Oil Purifiers

remove from used lubricating oil the water and dirt which are the forerunners of sludge and emulsion—the two chief causes of trouble in turbine lubrication. They do this by centrifugal force in a positive, mechanical way, so that the purity of the purified oil is never in doubt.

There is no longer an excuse for allowing sludge and emulsion to wear down your machines. The De Laval Oil Purifier ends trouble from dirty oil, and incidentlly saves oil by keeping it in service longer.

A Jointless Gastight Furnace Lining

The resistance of a furnace or firebox lining is weakest at the exposed edges of the brick, and may be remedied only in one of two ways: first, by setting the brick in Sternson No. 30 High Temperature Cement, or, secondly, by eliminating all edges and building a one-piece lining with

STERNSON NO. 40 MONOLITH

There can be no cracks where Sternson No. 40 Monolith is used. It withstands over 3,000 deg. F. and is not only more satisfactory and economical in operation, but is actually lower in cost than the old way of firebrick and mortar.

It is invaluable for repair work and is often used on the side wall without drawing the fire.

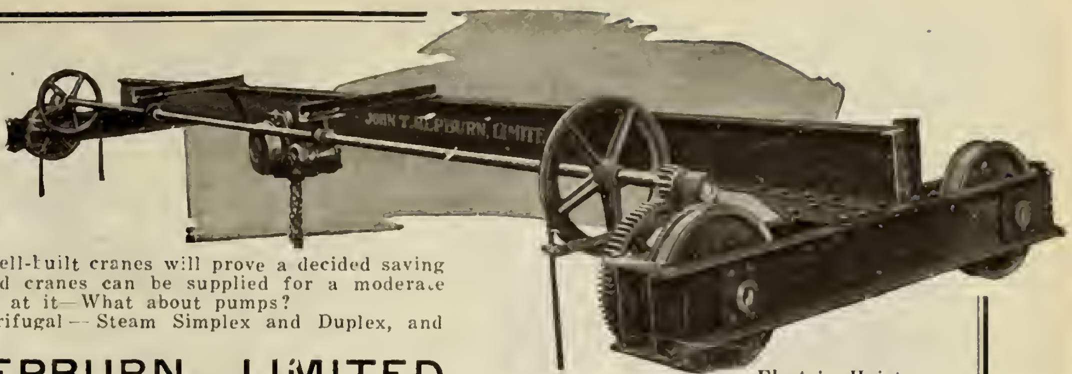
HEPBURN CRANES



Electric Hoist or Chain Block

These easily manipulated, well-built cranes will prove a decided saving in the Power House. Hand cranes can be supplied for a moderate outlay. And while you are at it—What about pumps? We make all kinds—Centrifugal—Steam Simplex and Duplex, and Power Pumps.

JOHN T. HEPBURN, LIMITED
Engineers and Iron Founders
18-60 VAN HORNE STREET - TORONTO, CANADA

Metallic Packing For Condenser Tubes

Makes tight condensers and stops tube faliures due to stresses of expansion and contraction. - Seals but does not bind tubes. Prevents electrolytic disintegration of tube ends by offering a path of low resistance between tubes and sheet. When over hauling or buying new condensers specify "JOHN CRANE" Process. Our text sent on request.

—and therein is the secret of never-leaking joints!

KEEP Smooth-On No. 3 handy and use it on every screw-thread joint. It fills the voids completely and never dries out or shrinks, therefore making a tight, never-leaking seal.

You avoid much future trouble and expense — with little effort and for little money — by making all screw-thread joints with Smooth-On No. 3.

Write for a free sample, and copy of the Smooth-On Instruction Book, which explains uses of other Smooth-On products.

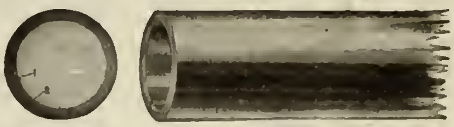
Smooth-On No. 3, identified by the gray label, is sold by supply houses everywhere in 5, 10 and 25-lb. tins. If not obtainable, tell us your dealer's name and we will see that you are supplied.

The Canadian Asbestos Co.
Dept. 52-H Montreal, Que.

SONDERGLASS

"The Unbreakable Boiler Gauge Glass"

Two Glass Tubes in One



The different metals used allow for expansion and changes of temperature to which the glass is subjected, and add greatly to its pressure-resisting qualities, as each of these metals has different degrees of expansion. The inside of the tube expands in proportion to the temperature of the steam or hot water and the outside according to the temperature of the air.

There are no others "Just as Good"

A Mallet and Trowel

AND A SUPPLY of Betson Plastic Fire Brick make the most durable boiler furnace lining, because it is all in one piece, free from cracks, seams, joints, moulded brick and fire clay.
Shipped either mixed ready for use, or dry to mix with water (the cost is the same) from our warehouses in principal cities.
How to obtain Greater Efficiency, more power from the fuel burned, and how to save about 50 per cent. on repair and upkeep costs are told in our booklet. Send for a free copy.

Write for valuable booklet.

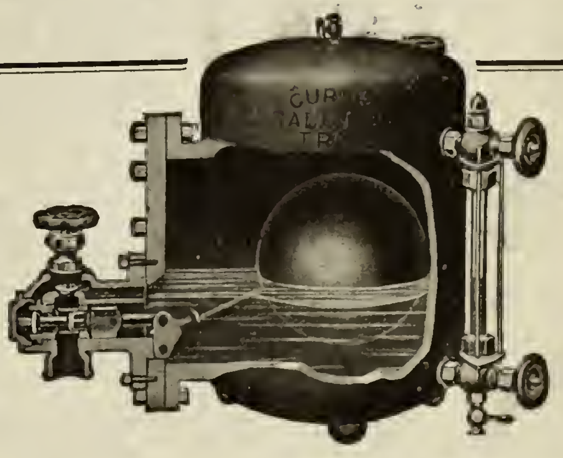
Curtis Engineering Specialties



Five Superior Features of the Curtis Trap

1. A perfectly balanced valve.
2. An absolutely frictionless valve.
3. The valve can be removed without breaking a joint, starting a gasket, or taking out a bolt.
4. The valve being frictionless and balanced, the whole power of the float is available for opening and closing the valve.
5. Each trap will operate perfectly on high and low pressures.

Send for descriptive circular of this trap.

The LOGIC of INSULATION

¶ The idea of insulating heat is a relatively new one. It was only a few short years ago that the practice of insulating heated surfaces began to be recognized as a thing worth while.

¶ And yet the theory of insulation is based on a simple fact which has been recognized by man as far back as his cave dwelling days; namely, that to conserve heat it pays to cover heated surfaces with a "blanket" or protection of some kind. This realization prompted the first wearing of clothing.

¶ That is the reason why today we put on heavy clothing and storm overcoats in winter weather—to conserve our body heat and energy.

¶ The heat generated in a boiler or furnace or kiln is as susceptible to atmospheric conditions as our own human bodies. A protecting "blanket" of insulation over the surface (or installed within the walls) of such equipment as boilers, furnaces, kilns, ovens, etc., serves directly as a guard against heat loss through the walls and tops.

¶ Sil-O-Cel Heat Insulation is furnished as Brick, Block, Powder and Cement, and is readily adapted for the insulation of any type or shape of equipment.

¶ The cost of insulation with Sil-O-Cel is generally paid for in fuel saving alone within six to twelve months of operation, and these savings continue each year through the life of the equipment.

MAGNOLIA

Magnolia Anti-friction Metal is the choice of thousands of engineers and machinists because it is always uniform in composition, dependable in service, melts and pours well, is widely adaptable, and assures cool running, efficient and economical bearings. Government tests prove it to have the lowest frictional coefficient of any known bearing metal. Write for test data

ANTI-FRICTION METAL

Stephen's Boiler Feedwater Treatment

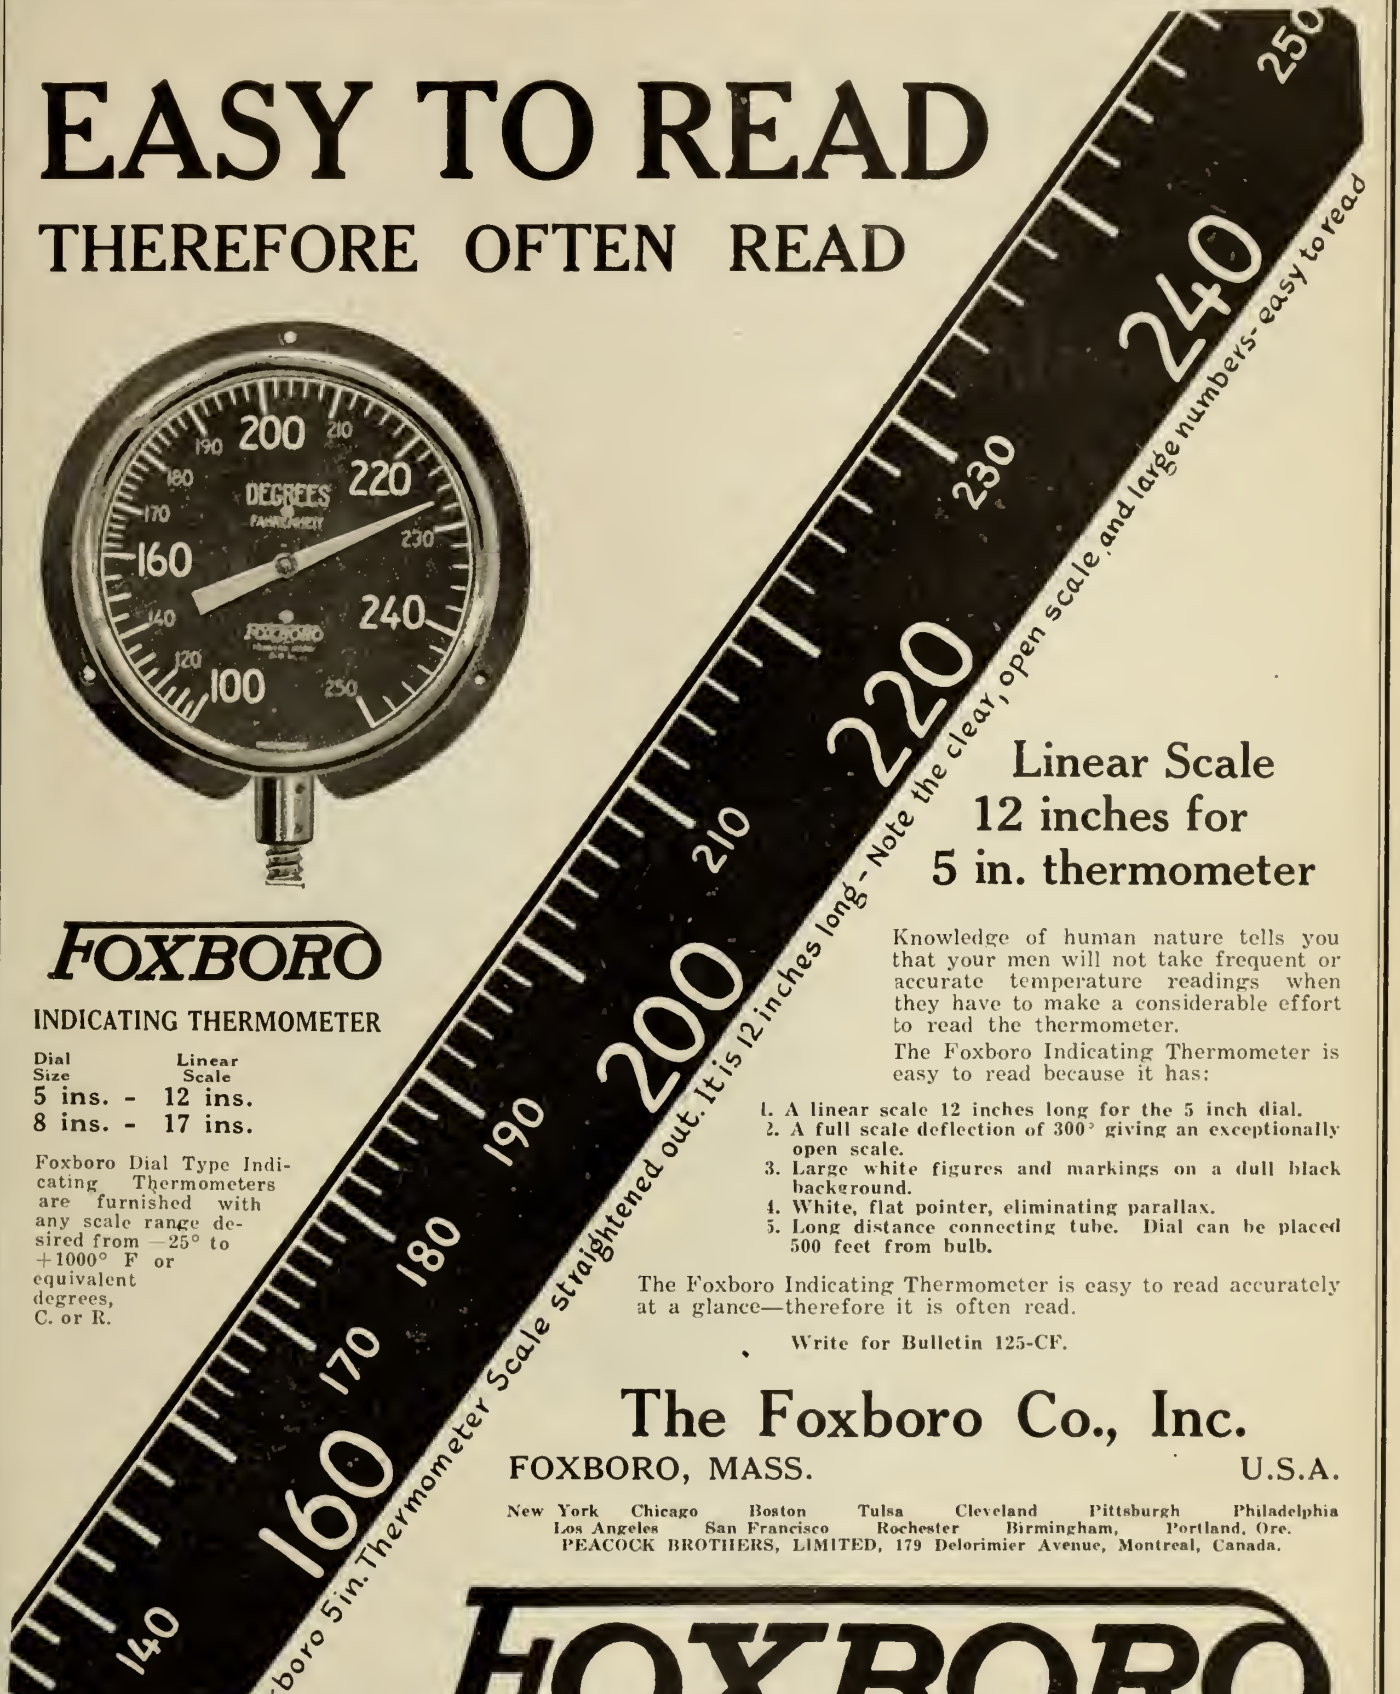
Don't endanger your boilers with old-fashioned, expensive methods which are often ineffective. You'll find that the Stephen's Feedwater Treatment is not only more economical but ensures the removal of old scale and prevents the formation of new scale in absolute safety.

Consult our engineers. They are always happy to discuss your feedwater problems in a practical way without obligation to you.

Stephen's Chemical Mfg. Co., Ltd., 2 Johnston St., Toronto, Canada

EASY TO READ

THEREFORE OFTEN READ



Here is the Foxboro 5 in. Thermometer Scale straightened out. It is 12 inches long - Note the clear, open scale and large numbers - easy to read

FOXBORO

INDICATING THERMOMETER

Dial Size	Linear Scale
5 ins. -	12 ins.
8 ins. -	17 ins.

Foxboro Dial Type Indicating Thermometers are furnished with any scale range desired from −25° to +1000° F or equivalent degrees, C. or R.

Linear Scale 12 inches for 5 in. thermometer

Knowledge of human nature tells you that your men will not take frequent or accurate temperature readings when they have to make a considerable effort to read the thermometer.

The Foxboro Indicating Thermometer is easy to read because it has:

1. A linear scale 12 inches long for the 5 inch dial.
2. A full scale deflection of 300° giving an exceptionally open scale.
3. Large white figures and markings on a dull black background.
4. White, flat pointer, eliminating parallax.
5. Long distance connecting tube. Dial can be placed 500 feet from bulb.

The Foxboro Indicating Thermometer is easy to read accurately at a glance—therefore it is often read.

MORRISON

Pressure Reducing Valves

Dependable Pressure Regulation

MAINTAINING correct reduced pressure on steam, air and gas lines is too important to be entrusted to valves of untried reputation.

More than 50 years of engineering experience is back of the Morrison Reducing Valve design.

Morrison Reducing Valves are furnished in all sizes with bronze or iron bodies for all ranges of pressure up to 300 lbs.

"Every Installation is a Demonstration of Merit."

Jenkins Automatic Equalizing Stop and Check Valves

Extra Heavy Iron Body Globe or Angle Patterns

These valves are designed to provide a wide margin of safety, being perfectly adapted to withstand the strains of high steam pressure and expansion and contraction of piping.

Each valve is tested to 800 pounds hydraulic pressure and guaranteed for working steam pressure up to 250 pounds.

If a tube should burst or other internal rupture should occur, valves will automatically shut off steam from the header to boiler.

Bodies and bonnets are made of high grade cast iron, spindles of manganese bronze—other mountings of best hard steam metal.

Detailed description will be found on page 85 of Jenkins Catalog No. 9—free on request.

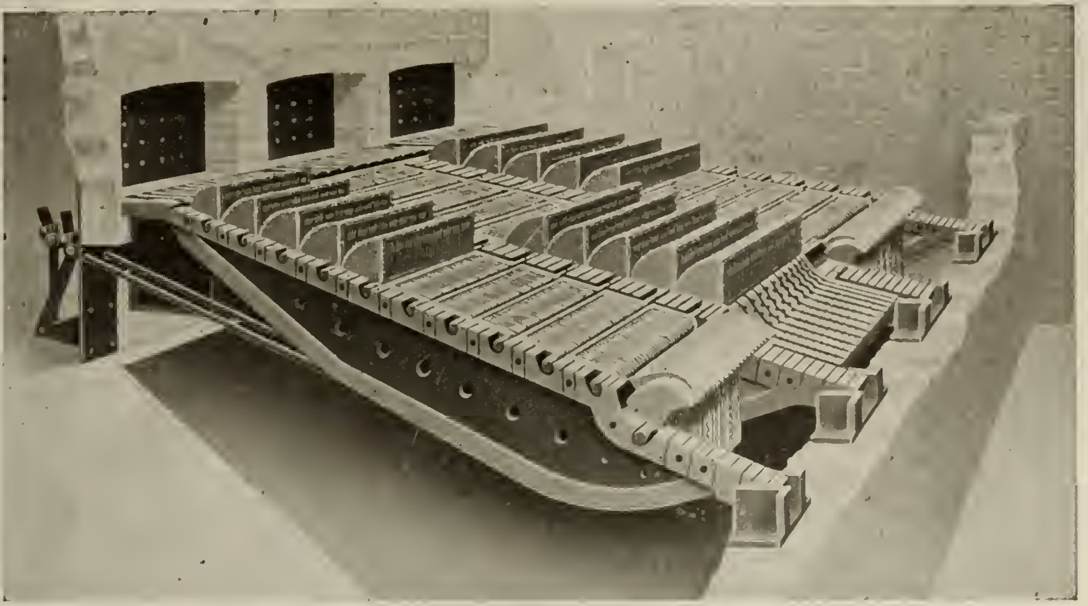
"Everything in the Boiler Room Except the Boilers"



THE FILES STOKER

Pays for Itself in One Year

Below is a copy of one of the many letters we have received, telling of the efficiency and economy of the Files Hand-Operated Stoker

Re FILES HAND STOKERS

Gentlemen:—

Frequently we receive letters from manufacturers, asking for information and our experience with the "Files Hand Stokers"—the most economical and efficient system of burning coal with the utmost conservation of labor.

As these inquiries are becoming more and more frequent, our better plan will be to furnish you with a letter to pass on, outlining our experience and satisfaction.

In September, 1920, we placed an order with you for two 150 H.P. Tubular Boilers, specifying our desire to have them equipped with "Files Hand Stokers." This we did on the recommendation of our United States Engineering Department, who had installed "Files Hand Stokers" in some seventeen plants, finding in them a decided saving and advantage over flat or shaking grates.

Speaking for ourselves, we have found them most satisfactory and economical, particularly so in regard to the elimination of smoke, rapid disposal of ash and clinker, thorough cleaning of fires without disturbing the active fire, and in maintaining an even bed of fuel.

We are able to keep a clean fire at all times, we have no cleaning period, for with the "Files Hand Stoker" the grate can be cleaned at peak load. It is only a matter of working one rod on each section, which can be done in less than two minutes.

The better the coal the better the result, but almost any kind of coal that will burn free can be used. With good coal, however, it is an easy matter to procure 150% boiler rating, which in reality is 12½ lbs. evaporation per pound of coal. Generally speaking, evaporation is around 7 or 8 lbs., and often as low as 5 or 6 lbs.

Our Files Hand Stokers have now been installed about two years, during which time they have paid for themselves twice over if we consider the saving in fuel.

And what we have done and are doing with them others can do.

We know they effect a saving; we know they are a convenience; they have proved satisfactory in every particular, and we have no hesitation in recommending them.

Yours very truly,
THE MERIDEN BRITANNIA CO., LIMITED.

Why not Profit by others' Experience?

Waterous

BRANTFORD, ONTARIO, CANADA

*5 Retort RILEY STOKERS installed under 487 H. P., G. & McC. boilers.
Smith, Hinchman & Grylls, Consulting Engineers, Detroit.*

More Steam at Lower Operating Cost

THE PROBLEM.

At the plant of Hiram Walker & Sons, Ltd., Walkerville, Ontario, more steam was required. Their boiler room contained 10—125 H.P. boilers. These boilers were economically fired but the plant layout in general was inefficient.

THE SOLUTION.

They replaced these *10* boilers with *3* of 487 H. P., fired by Riley Stokers which now gives them ample steam capacity. Although the normal boiler H.P. is increased but little the *actual* capacity is about three times greater because the Riley Stokers will operate the boilers up to 250% of rating or more. *When the above picture was taken two of the boilers were making 200% of rating.*

THE RESULT.

Greatly increased capacity with a *reduction in operating expenses.* The improved power plant layout with automatic coal and ash handling equipment and Riley stokered boilers has made possible a reduction in labor from 8 men to 2 men per shift. This saving in labor alone amounts to nearly $100 per day.

Find out what the Riley can do for you. Ask for the catalog.

"To economize, Cochranize"

The Cochrane Hot Process Water Softener

Saves Time, Money & Labor—Let Us Show You

A Satisfied Customer—Our Greatest Asset.

Shortly after installing a Cochrane Softener, a pulp and paper company wrote us as follows:

"Your letter re water softening plant received some days ago and must say the plant is working O.K. It is keeping the clean boilers clean and cleaning the dirty ones.

Six months later a second letter was received, as follows:

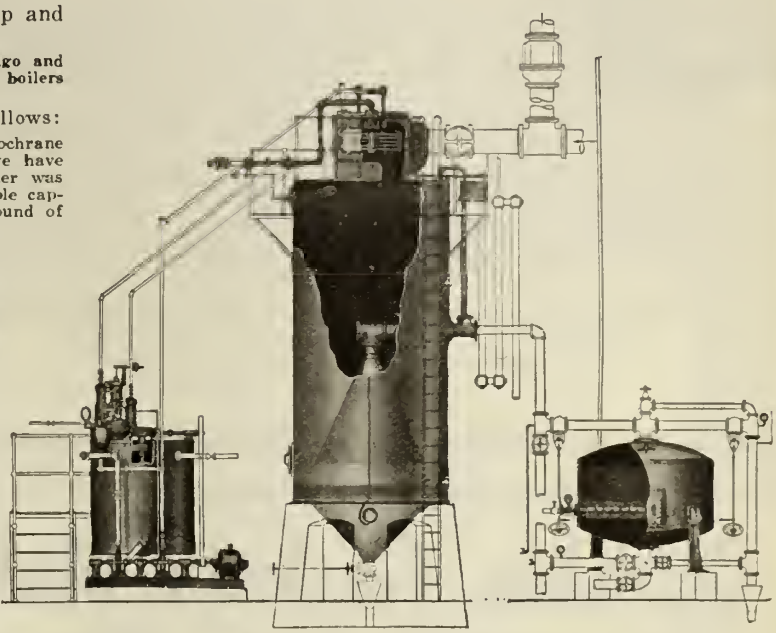
"On August 9th, 1921, we started up the 18,000 G.P.H. Cochrane Hot-Process Water Softener in our boiler room, and while we have no exact data as to our performance before this water softener was installed, I can state that it has added materially to our possible capacity in B.H.P. and has also increased the evaporation per pound of coal.

"We can now operate our boilers at a continuous rating of 200 per cent. for six months without cleaning, and at the end of that time when a boiler is opened, we find only a small amount of sludge, which can readily be washed out with water, whereas, with raw water, at the end of six months we used to get 3000 lbs. of scale from a boiler, taking two men three weeks, working 9 hours per day to clean.

"Since installing this water softener we have not had to put in any new tubes. We have no deposits in the feed lines and the feed water leaving the filter is always crystal clear; but, as a matter of fact, we never did have deposits in feed lines, as our raw water is clear but hard. For the six months that we have used treated water we have not noticed any deposits in steam lines and do not anticipate any.

"The attention required by this plant takes about one hour in the morning and one hour in the evening of one man's time, and we have not increased our staff to take care of the apparatus.

"The great benefit we derive from this plant is clean boilers all the time. Before installing this water softener we always had one or two boilers down for new tubes or cleaning. The cleaning was a long, hard job, as the scale was very hard. Now we can operate all our boilers all the time, if necessary, as far as the cleaning is concerned."



Cochrane Hot Process Water Softener, complete with Chemical Reagent Tank, Flow Proportioner and Sand Filter.

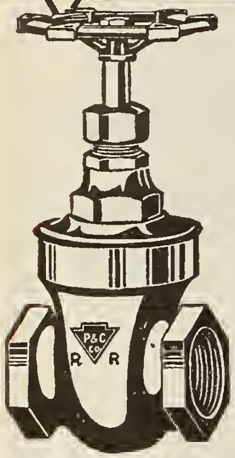
PRATT & CADY VALVES



Every part of these valves is easily renewable without removing valve from pipe line.

No Chance of Leakage with Pratt & Cady Bronze Gate Valves

with renewable seat-rings

Pratt & Cady Bronze Gate Valves are the ideal valves for steam, water, air and gas lines. They have two chances of being tight where any Globe Valve has one chance.

All seat rings are independent rings of bronze, or any special metal or material best adapted to the service for which the valve is to be used. They can be easily renewed. The gate is a double-faced, wedge-shaped casting with side grooves by means of which it slides on guides in the valve body.

Great pains are taken in the machining of all parts of these valves to insure their accuracy and interchangeability. The wedge can be taken out of the valve and replaced with the opposite faces in contact, and will fit accurately. Being double-seated these valves can be used with the pressure applied at either end.

Imperial Greases.

Hundreds of Canadian firms have used Imperial Lubricants exclusively for years. The fact that we manufacture a grade of oil or grease for every lubricating requirement and always maintain the same standard of quality and service, makes it easy and profitable for you to standardize on Imperial Lubricants.

Write our nearest branch for the advice or service of an expert lubrication engineer.

How Do You Know Instructions Are Being Followed?

From a study of Bristol's chart records, it has been possible to establish a process that is most resultful. By a continued study of the records of

TRADE MARK
BRISTOL'S
REG. U. S. PAT. OFFICE.

Recording Pressure Gauges

you can tell whether this efficiency is being maintained — whether your instructions are being followed.

The marked simplicity of Bristol's instruments, is the chief reason why our recording gauges operate continuously for years, with little attention and few repairs. Catalog 1006-A is waiting for your request.

High Powered Gasoline Engines on Centrifugal Pumps, Air Compressors, Shovels, Locomotives and Electric Generators

Sterling
THE ENGINE OF REFINEMENT

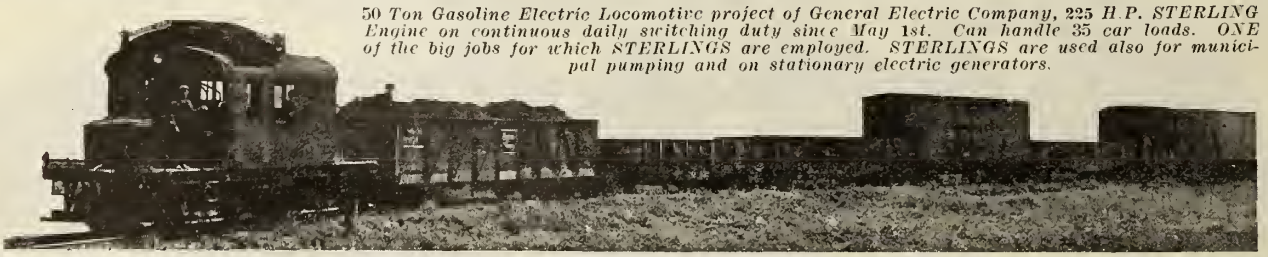
Because—

- They cost less than any other form of power.
- Are cheaper to run than a steam plant, particularly in isolated districts.
- Are easily transported, readily installed.
- Can be run by any intelligent engineer.
- Are built in **large** sizes for big pumps and generators.

The contractor with this equipment carries the smaller investment, can work faster, with less labor, finish the job sooner; underbid the other fellow and handle more jobs at a profit. The city or manufacturer that uses STERLINGS for emergency has an unfailing source of power.

Send for a Catalog.

Sterling Engine Co. (Dept. C4) Buffalo, N.Y., U.S.A.



50 Ton Gasoline Electric Locomotive project of General Electric Company, 225 H.P. STERLING Engine on continuous daily switching duty since May 1st. Can handle 35 car loads. ONE of the big jobs for which STERLINGS are employed. STERLINGS are used also for municipal pumping and on stationary electric generators.

Let the Users Give the Evidence!

Fisher Reducing Valves are exceptionally sensitive and accurate. More than that, they are so simple in principal and honor-built in construction that they continue to give perfect satisfaction when you might expect them to be worn out.

Here are two examples from Canada of the wonderful service they give:

> "Fisher Reducing Valve purchased from you in 1904. We wish to say that this valve is connected to a 4½ x 2¾ x 4 duplex pump, used for pumping pickle. An air pressure of 40 lbs. is used on the diaphragm and the valve will start and stop the pump and maintain a constant pressure within 2 lbs. with very little attention. The valve has been in daily operation since we purchased it and the results we have received have been most satisfactory."
>
> THE INGERSOLL PACKING COMPANY, Ltd.,
> Ingersoll, Ont.

> "Regarding Fisher Reducing Valve purchased from you on Sept. 3rd, 1907. This valve is in use and has given us very good service. We have had to renew the valve and seat a few times, but these repairs were inexpensive. We like the valve on account of its simplicity and reliability."
>
> P. BURNS & CO., Ltd.,
> Calgary, Alberta.

Hundreds of letters like these are in our files. That kind of evidence means something to every buyer of power plant equipment.

Our Bulletin No. 201 gives full information about Fisher Reducing Valves. Let us send it to you.

FISHER
Reducing Valve

(Type 11--A)

It Can't Air-Bind!

When steam is shut off the Steam Trap Sarco opens automatically and stays open until steam is again applied—then the steam forces all the air out and closes the trap until condensation again opens it. No air or water can stay in the trap.

Consequently the Sarco cannot freeze.

Steam Trap Sarco keeps the lines drained at all times. There is no big body of water in the trap to cool the steam and reduce it to liquid.

Has only one moving part. No levers, gauges, stuffing box, etc., to corrode or gum up and stick, and cause the trap to stay open and waste steam.

Can be screwed into pipe line at any angle and takes practically no space. No platform, pit or support needed.

Although the Sarco has many exclusive advantages, it costs but one-third as much as most traps.

Try a Sarco 30 days free.

What Makes One Door Better Than Another?

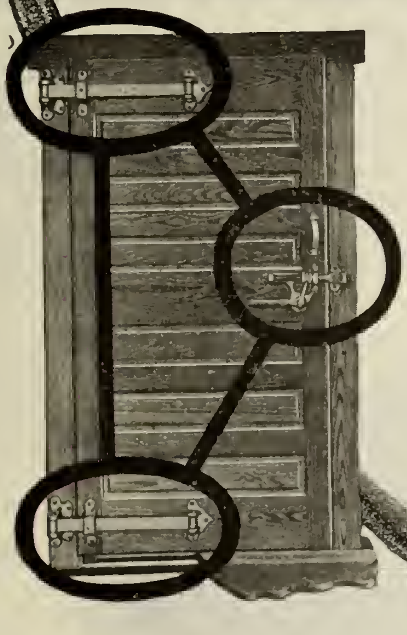
WITH "Your Plant Only as Good as Your Door," it is an equal fact that the door itself is only as good as its **hardware.**

In the **hardware** lies one door's advantage over another! It is on the hardware that the door swings. It is the hardware which is responsible for efficient shutting. The difference in hardware helps to make the difference in doors.

Jamison Cold Storage Doors—sturdily built of heavy materials and properly insulated—are fitted with hardware embodying patented features owned exclusively by us—hardware heavy enough to "carry the load" and complete the job of the door. Hardware that is guaranteed against breakage in line of duty. Hardware that keeps your plant "**in** commission" and **out of repair shops,** with attendant loss of time and money.

BETTER REFRIGERATION
JAMISON
HAGERSTOWN MD. U.S.A.

Adjustable Spring Hinges and Automatic Self-Tightening Fasteners are some of the Jamison "Strong Points."



Both of these "strong points" are exclusively Jamison's. The Adjustable Spring Hinges enable you to keep the door forced tight against the double seals of contact at all times — regardless of shrinking, swelling or wear — through the process of a simple adjustment.

The Self-Tightening Fastener is a massive device of great strength and power that requires but a slam of the door to force it perfectly tight, at the same time exerting constant inward pressure on the door. This Fastener closes the door to stay — it cannot reopen through the force of a slam!

Catalog No. 10 fully describes the various Jamison Patents which give Jamison Products their superiority. You'll find it interesting. Copy will be mailed upon request. Write to "Desk 11," Please.

HAMILTON, ONT.

Don't Fall Behind Your Competitors

Sometimes you wonder why your competitor's plant seems to run just a little more efficiently than yours—with fewer breakdowns, shut downs and incidentally they seem to get their selling prices below yours a little too often. Just take thought to your Boilers at this point—maybe the trouble is there. Remember, a high-grade, modern economical Boiler—such as we make—can effect steam, water and coal savings (to say nothing of avoiding repair costs) and call for fewer men to stoke and run them, in a way that will surprise and delight you, and make for a smoother running plant all through.

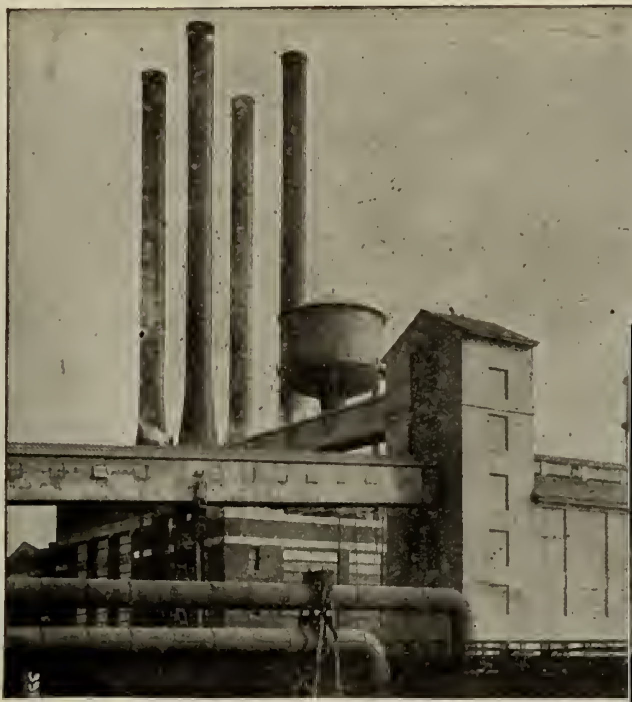
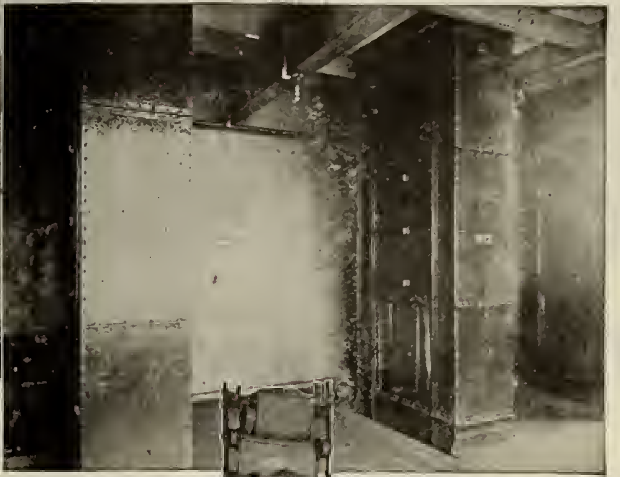
At the Ford River Rouge Plant



A Jeffrey Pivoted Bucket Carrier



THE economy and efficient performance of Jeffrey Conveying Equipment is very evident at the Ford River Rouge Plant.

Here in the pulverizer building, 250 tons of coal per hour are ground into boiler fuel. It is then conveyed through the pulverizer building up to the tower by a Jeffrey Pivoted Bucket Carrier on to the cross conveyors into the boiler room.

In the Ford Plant and in hundreds of industrial power plants Jeffrey Equipments are important factors in lowering the cost of generating power.

Jeffrey Labor—aiding Coal and Ashes Equipments include Track Hoppers, Feeders, Crushers, Conveyors, Elevators, Skip Hoists, Weigh Hoppers, Portable Loaders and Unloaders, Portable Belt Conveyors, etc.

THE FIREPROOF VENTILATING FLOORING

A floor of Irving Subway is permanently smooth, yet permanently non-slipping—a paradox hard to be grasped except by those who have had actual "foot experience" with this open steel flooring. There is all the shock-resistance and wear-resistance needed to stand hard service—and yet that comfortable, foot-gripping surface is never lost. Safety and comfort are inbuilt features of this all-steel open flooring—as lasting as the structure of the Irving Subway. Let us send Catalog 3A50.

The government-proved bearing metal

Magnolia Anti-friction Metal has been proven by United States and foreign government tests to have the lowest frictional coefficient of any known bearing metal. This fact alone clearly establishes its superiority to ordinary babbitts.

And there are additional reasons for the wide popularity of Magnolia Metal. It melts and pours well, is easily peened and scraped in, is always uniform in composition, adapts itself quickly to shaft inequalities and gives long and dependably good service.

A single trial will quickly prove the advantages of Magnolia Metal. If your dealer can't supply you, write direct to our nearest office. 20

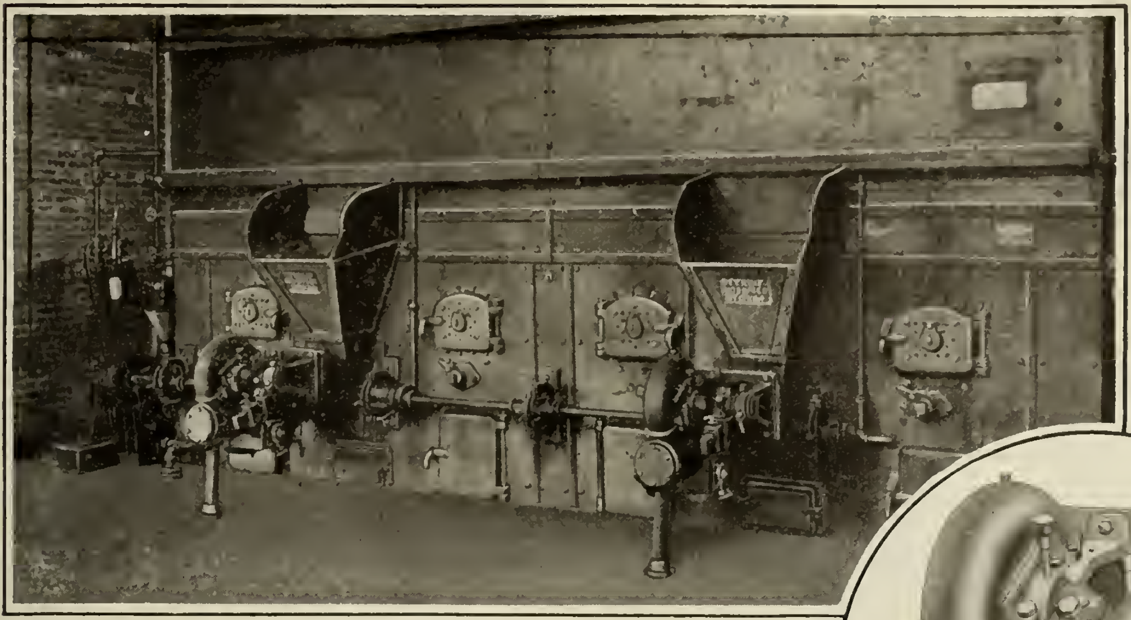
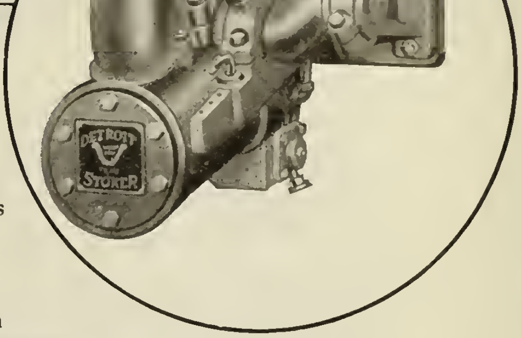
SUPERIOR DESIGN and CONSTRUCTION

Detroit Single Retort Underfeed Stokers





Built Heavy for Hard Service and Durability

You will find that the design and construction of Detroit Underfeed Stokers sets new and higher standards in the manufacture of stokers.

For example, note such construction details as:

GEAR CASE: The reduction gears and worms are assembled in an enclosed gear case, with anti-friction roller-bearings, easily accessible, fully enclosed, free from dirt, and running in oil.

REDUCTION GEARING: The design and construction of reduction gearing presents a distinct advance over current stoker practice. The train consists of two sets of heavy worm gear reductions, the smaller being *made of bronze*. Both gears are machined and the worms are cut from drop steel forgings.
